Her husband Syphax, king of W. Numidia, who sided with Carthage in the second Punic War, was defeated in 203 B.C. by another Numidian king, his neighbour Masinissa, an ally of the Romans. Sophonisba passed into the hands of the victor, who made her his wife, but was ordered by Scipio, the Roman general, to give her up. Masinissa, however, had become much attached to her, and sent her poison with which she put an end to her life. Sophonisba is the subject of tragedies by Marston, 1602; James Thomson, 1729; Corneille, 1663; Alfieri, 1783; and others. *See* Masinissa.

Sophora. Genus of trees, shrubs, and a few herbs belonging to the family Leguminosae. There are about 25 species, natives of the warmer regions of Asia and America. The leaves are broken up into two rows of paired leaflets, and the purple, yellow, or cream-coloured, pea-like flowers are borne in racemes or panicles. The best known species is *S. japonica*, the Chinese pagoda tree. *S. tetraptera*, a yellow-flowered species from New Zealand, is only half-hardy in Britain, and will only grow when trained against a warm sheltering wall. *S. sericea*, native of the North American prairies, is a perennial herb, covered with silky down, and having white flowers. *See* Pagoda Tree.

Soprano (low Lat. *superanus*, sovereign). The highest kind of human voice. Its compass is shown thus:

but exceptional voices can go nearly an octave higher. The classification, however, depends as much upon the quality, which is of light timbre, as upon the range. It belongs naturally to

women and boys, but during the 17th and 18th centuries in particular, it was also possessed by artificial sopranos (*castrati*), who united with the lung power of men the timbre of the boy's voice. *See* Singing.

Sopron or ÖDENBURG. Town and co. in the extreme N.W. of Hungary. The town lies W. of the Ferto and is a rly. junction for Vienna, 51 m. N.W. Its chief buildings are the Dominican church of the 17th century, Benedictine church of the 13th century, town hall, which houses a museum, and town tower, 200 ft. high. The site has been identified as that of the Roman Sopronium. Pop. est. 35,000.

Sopwith, THOMAS OCTAVE MURDOCH (b. 1888). British airman, yachtsman, and inventor. Studying at Seafield engineering college, he became interested in aeroplane designing, and in 1910 won the Baron de Forest £4,000 prize for a flight from England to the Continent. Then he founded his own aviation and engineering company at Kingston-on-Thames, where he designed and built such aircraft as the single-seater Pup and a triplane, both used in the First Great War. In turn managing director of the Hawker Engineering co., director of Hawker Aircraft Ltd., and chairman of Hawker Siddeley Aircraft Ltd., he helped to evolve aircraft outstanding in the Second Great War—the Hurricane, Typhoon, and Tempest. In 1934 Sopwith challenged with his yacht Endeavour for the America's Cup, but was beaten by H. Vanderbilt's Rainbow.

Sora. City of Italy, in the prov. of Frosinone. It stands on the Liris (Garigliano), 62 m. E.S.E. of Rome. Woollens and paper are manufactured; there is some trade in wine, olive oil, fruit, and cattle. Originally a Volscian town, Sora was colonised by the Romans in 303 B.C., and has remains of its old walls, and ruins of medieval castles on an eminence above the town.

Sorata. Andean mt. in the dept. of La Paz, Bolivia. It stands E. of Lake Titicaca and rises to the peak of Illampu to the highest point in the country, 21,490 ft. Sorata is also the name of a health resort on the lake at the base of the mt. Pop. 3,500.

T. O. M. Sopwith, British airman

Sorau (Pol. Zary). Town 60 m. S.S.E. of Frankfort-on-Oder, near the boundary of Brandenburg and Silesia, in the area of Germany placed under Polish rule by the Potsdam agreement, 1945. With urban rights from 1260, it was governed by counts, but fell to Saxony in 1765 and to Prussia in 1815. There are a 13th century castle, three Gothic churches, and a palace of 1710-16. Normally there are glass, porcelain, and textile industries. Pop. 20,134.

Sorauren, BATTLE OF. Engagement in the Peninsular War, July 28, 1813. The fiercest of the Pyrenees battles, it was the culmination of Soult's advance to relieve San Sebastian. Wellington's allied forces numbered some 12,000, and Soult attacked with double that number. The French, unable to move the British from their lines, were forced to withdraw. Two days later another engagement took place at Sorauren as Wellington was driving Soult back across the Pyrenees. See Peninsular War.

Sorbonne. French centre of education. It was founded by Robert de Sorbonne in 1252 as a hostel for poor students of the university of Paris belonging to

secured the imprisonment, and finally the execution, of Étienne Dolet, the Lyons printer, on grounds of heresy and contumacy, it had previously encouraged other early printers, including Ulric Gering (Quering), until the flood of new books threatened to get beyond control. Many world-famous authors, from Rabelais to Rousseau, fell under the ban of the Sorbonne, which supported the Jansenists against the Jesuits, while it was the favourite butt of all the writers who desired emancipation from the rigid control of ecclesiastical authority.

Among the benefactors of the Sorbonne was Richelieu, who completed his theological training there, after being consecrated by the bishop of Luçon. In 1629 he erected new buildings for the Sorbonne, which remained in use until the vast reconstruction scheme of 1885 onwards. The only part of the 17th century buildings now standing is the church, where the cardinal was buried. Restored by Napoleon in 1808, the Sorbonne since 1896 has been the university of Paris. The New Sorbonne is housed in a magnificent range of buildings, with a frontage of 270 yards. It still attracts numbers of foreign students.

Sorcerer, THE.

Comic opera in two acts by Gilbert with music by Sullivan. Produced at the Opéra Comique, London, Nov. 17, 1877, it was the earliest full-length opera of the famous collaboration, though shorter than any which followed.

The setting is a rural village and the theme is the

action of a love philtre. The most memorable song is the patter-song in which the sorcerer, John Wellington Wells, introduces himself to the company.

Sorcery (Lat. *sors*, a lot). Originally a simple form of divination by casting lots. The term later came to signify the exercise of supernatural powers by a magician over spiritual agencies. It was also applied to the practice of magic generally. Up to about the middle of the 18th century, sorcery in England was a crime punishable with death. See Asia; Divination; Lot; Magic; Witchcraft.

Sordello (13th century). Italian troubadour. He is supposed to

have been born at Goïto, near Mantua, and after some rather scandalous behaviour to have taken refuge, about 1230, at the court of Charles of Anjou, and to have died in Provence about forty years later. Several of his love songs and political poems have been preserved. They were collected and published with a biographical sketch in Italian by C. de Lollis, 1896. There are several references to him in Dante's *Purgatorio*; and Robert Browning made Sordello the subject of one of his earliest long poems, 1840.

Sorel. Town of Quebec, Canada, capital of Richelieu county. It stands at the junction of the Richelieu with the St. Lawrence, 51 m. N.E. of Montreal, on the C.N.R., with ferry connexion to the C.P.R. There are shipbuilding yards and sawmills, and manufactures of agricultural implements, wooden goods, bricks, etc. Sorel was founded in 1665, one of the oldest towns in Canada. Pop. 12,251.

Sorel, AGNES (1409-50). Mistress of Charles VII of France. Of good family, she was born at Fromenteau in Touraine, and entered the service of the duchess of Anjou, who in 1431 brought her to the royal court. She attracted the notice of Charles, and in 1444 became his mistress. She received great gifts from the king and remained his companion until her sudden death, which the dauphin, afterwards Louis IX, was said to have caused. See Orléans; consult *The Lady of Beauty*, J. D'Orliac, 1933.

Sorel, ALBERT (1842-1906). French historian. Born at Honfleur, Aug. 13, 1842, he was educated in Paris and in Germany. Abandoning the law, he became a civil servant 1866-75, but his main interests were literary, and he was soon at work on volumes of prose and verse. His life-work, however, was done in the domain of history. He had already lectured on diplomatic history at the college of political science when the first volume of his *Europe* and the French Revolution appeared in 1885. In 1904 he published the eighth volume of this great work. He died in Paris, June 29, 1906.

Sorel, CÉCILE (b. 1875). French actress. Born in Paris, Sept. 7, 1875, she first appeared at the

Sorbonne, Paris. A view of the courtyard of the University of Paris

various nations, under the title of the community of poor masters. The Sorbonne soon gained a fame and authority in theological matters, which lasted until its temporary suppression at the Revolution. Royal patronage and support secured a house for the new focus of learning in 1257, in the Latin quarter of Paris, where the present institution is to be found, and the name Sorbonne was for centuries a rallying cry for all the anti-liberal forces of the Church, and bitterly hated by the friends of the Reformation and the new learning.

The faculty of the Sorbonne soon became all-powerful in its decisions, and it is curious that while it

Agnes Sorel, Mistress of Charles VII of France

Eden Theatre there, establishing her reputation in classic drama. She acted at the Odéon, 1893-1901, and first appeared at the Comédie Française, 1901. A supreme exponent of comedy, she achieved an international reputation, frequently acting in Molière. She married the Comte de Ségur.

Sorghum. Genus of grasses of the family Gramineae. They are natives of the warmer regions, with the flowers in panicles and each glume containing two flowers. The principal species is Indian millet (*S. vulgare*). There is a variety *saccharatum* of this species, from whose stems a syrupy sugar is obtained. *S. halepense*, with broad, white-ribbed leaves, is often cultivated for ornament in British gardens, its loose purple panicle attaining a height between 2 ft. and 10 ft. See Indian Millet.

Soria. Prov. of N. Spain. It occupies 3,977 sq. m. between the Sierras de Guadarrama, de la Demanda, and Moncayo. A mountain-bordered tableland in the basin of the Douro, it has a cold and dry climate. The snow-capped mountains are forested with oak and beech on the lower slopes. Lumbering, charcoal-burning, and working of asphalt and salt are main occupations. Pop. 162,218.

Soria. Town of Spain, capital of Soria prov. Situated 155 m. N.E. of Madrid, the town, which has a mediæval aspect retaining parts of the 13th century walls and several ancient palaces, stands at an elevation of 3,465 ft. on a bleak plateau. Here the Douro is crossed by a massive bridge. The collegiate church of San Pedro and a ruined castle are the most notable edifices. Flour mills, tanneries, potteries, linen, and chocolate factories are the principal industrial establishments, while leather, fruit, timber, and wool are the main articles of trade. The site of the ancient Numantia is 3 m. N. Pop. 7,500.

Soriano. Dept. of Uruguay. It is bounded W. by the Uruguay river and N. by the Rio Negro, and has an area of 3,561 sq. m. Stock-rearing is the principal occupation. Mercedes is the capital. Pop. 93,490.

Sorites (Gr. *sōros*, heap). In logic, a series of syllogisms in which the predicate of each proposition is the subject of the following proposition, the conclusion containing the subject of the first, and the predicate of the last proposition; the soul is a thinking agent; a thinking agent is indivisible; that which is indivisible is indestructible; therefore the soul

is indestructible. See Logic; Syllogism. Pron. sō-ri-teez.

Sorø. Town of Denmark. It stands on Lake Sorø, in Zealand, 49 m. S.W. of Copenhagen and 20 m. E.N.E. of Korsør, with both of which towns it has rly. connexion. The tombs of several Danish kings and of Holberg, the dramatist, are in the church attached to its famous Cistercian monastery. Sorø academy, founded 1586, is one of the wealthiest institutions of its kind in Europe.

Sorø or **Soroy.** Island of Norway, lying off the N.W. coast, some 20 m. N. of the mouth of Alten Fjord. Its greatest width is about 40 m. The pop. of about 2,500, mostly engaged in fishing, suffered extreme hardship at the hands of the German forces during the Second Great War. In Nov., 1944, they were ordered to evacuate the island. All houses, animals, and food stocks were destroyed, and over 1,000 men and women were removed for forced labour. In 1945 it was announced that 525 civilians had been rescued from the island in three Royal Navy destroyers and the Canadian destroyer Sioux.

Sorocaba. City in the state of São Paulo, Brazil, one of the chief industrial centres of the republic, lying 68 m. W. of São Paulo. Besides having large cotton and silk weaving and spinning mills, it produces alcohol, boots and shoes, cement, fertilisers, and wines. There are rly. workshops, orange groves, and packing plants, all served by hydro-electric power. The district is an important cotton-growing centre. Rly. connects the city with São Paulo. Pop. 42,000.

Sorolla y Bastida, JOAQUIN (1863-1923). A Spanish painter. Born at Valencia, Feb. 27, 1863, he studied art under Pradilla and in Paris. In 1900 he was awarded the grand prix of the Paris Salon, and soon came to be recognized as the foremost painter of Spain. A brilliant Impressionist, he produced an immense number of pictures, chiefly landscapes and marine pieces with groups of fishermen and children. He also painted portraits of the Spanish royal family and others. He died Aug. 10, 1923. See Spain: Art.

Soron. Town of the United Provinces of India, in the Etah division. Situated in the N. of the div. near the Ganges, it is a pilgrim resort and contains the temple of Sita Ramji and the tomb of Sheik Jamal. Pop. 13,000.

Soroptimists. Feminine counterpart of the Rotarians. This body of business and professional

women with Rotary ideals of public service was founded at Oakland, Calif., in 1923, the name indicating literally "sisterhood of the best." There are numerous Soroptimist clubs in Great Britain with membership exceeding 6,000. Weekly, fortnightly, or monthly meetings are held by British Soroptimists to hear addresses and conduct discussions, and an annual summer conference reports progress. An international conference takes place every four years.

Sorority. Society or club of students in a women's college in the U.S.A., corresponding to a fraternity in a men's college and with similar objects. It may be either nationally chartered or a single chapter in one college. In 1948 there were 29 general sororities, with memberships from 200 to over 43,000. The earliest was founded in 1851. There were also 26 professional sororities, confined to members of professions, such as architecture and music, and six education sororities. Each society is denoted by two or three letters of the Greek alphabet.

Sorpe Dam. Structure in the Ruhr valley, Germany, supplying hydro-electric power to surrounding districts. It was attacked in the Second Great War by R.A.F. bombers for the first time on May 17, 1943, when the Mohne and Eder dams were breached. It withstood this attack, and also a 12,000-lb. armour-piercing bomb which struck it when dropped by the R.A.F. on Oct. 15, 1944.

Sorrel (*Rumex*). Large genus of biennial and perennial herbs of the family Polygonaceae, including the dock (*g.v.*). The two smallest British species are known as sorrels, and are weeds in every meadow and pasture. Their leaves are edible, have a pleasant acid flavour, and are used as a salad ingredient. For this purpose seed should be sown in spring in rich loam, and the plants thinned out

about 2 months afterwards to a distance of 6 ins. apart every way. Sorrel may be increased either by seed or by the division of the roots in March. The British sorrels are *R. acetosa* and *R. acetosella*; an Italian species, *R. patientia*, is sometimes grown for use as a herb.

Sorrel. Leaves, flowers, and stems of *Rumex acetosa*

Sorrel Tree. Flowerspray and lanceolate leaves; inset, single flower

Sorrel Tree OR **SOURWOOD** (*Oxydendron arboreum*). Tree of the family Ericaceae, indigenous to N.E. America. It has oblong lanceolate leaves and clustered sprays of white flowers. The names refer to the acid taste of the leaves.

Sorrento (anc. *Surrentum*). City of Italy, in Naples prov. It is a tourist resort picturesquely situated on a promontory between the Bays of Naples and Salerno, 16 m. S.S.E. of Naples and 10 m. by road S.W. of Castellammare. It contains ruins of Roman temples, a cathedral, and a seminary. Torquato Tasso, a native, is commemorated by a marble statue. Sorrento wine is celebrated. The Allied 5th Army gained possession from the Germans of Sorrento, undamaged, Sept. 28, 1943. Pop. (est.) 7,000.

Sortes Virgilianae (Lat. *sorts*, a lot). Practice of divination by opening a sacred book and taking the first words on which the eye falls as a supernatural indication or warning. The Sibylline books were used for this purpose by the Romans, and after their destruction were succeeded by Virgil's Aeneid, whence the term is derived. See Divination; Lot.

Sör-Trøndelag. Fylke or co. of Norway. It stretches S. from Trondhjem Fjord to the Dovrefeld lying between the co. of More and Sweden. Trondhjem and Røros are the chief towns. Its area is 7,241 sq. m. Pop. 192,151.

S O S. Morse signal issued by vessels in distress, usually by radio. The letters are not abbreviations of words, but are used because they are the most distinctive in the Morse code and the easiest to transmit (three short signals, three long, three short). At sea normal radio traffic ceases for a specified period each hour to enable ships to listen for distress messages, while the signal itself usually can be detected when superimposed on traffic using normal

ship's wavelengths. On vessels which do not maintain constant radio watch, reception of the Morse code actuates an automatic device on the radio receiver and rings a bell on the bridge and in the operator's quarters.

The term SOS is also used for an emergency message broadcast by the B.B.C. The first of these was sent out on Sept. 10, 1923, and they now average 1,000 a year. Messages are restricted to two types: those requesting relatives to go to a sick person, broadcast only on a medical certificate and when all other means of communication have failed; and police messages calling for witnesses of accidents or announcing the loss of dangerous drugs.

Sosnowiec OR **SOSNOVETS**. Industrial town in Polish Silesia. It lies 7 m. E. of Katowice, with which there is rly. connexion, in the most populous area of Poland, and before the Second Great War had some 130,000 inhabitants, engaged chiefly at iron and chemical works and cotton mills. Its river is the Brinitza.

Soteriology (Gr. *soteria*, safety; *logos*, knowledge). In Christian theology, term for the science or doctrine which treats of salvation through Jesus Christ. It is to be distinguished from Christology (*q.v.*), which is concerned with the person of the Redeemer. See Salvation.

Sotheby's. London firm of auctioneers of books and works of art. Founded by Samuel Baker, in York Street, Covent Garden, where its first auction was held Jan. 7, 1744, and carried on by his nephew, John Sotheby, the firm became known later as Sotheby, Wilkinson and Hodge, and its catalogues have included many famous collections. After nearly a century of occupation, the rooms in Wellington Street, Strand, the scene of a destructive fire June 29, 1865, were given up May 25, 1917, and new premises were opened on the site of the old Doré Gallery in Bond Street.

Sothern, EDWARD ASKEW (1826-81). British actor, born April 1, 1826, in Liverpool. He made no mark as an actor until the production of Tom Taylor's *Our American Cousin*, in New York, May 12, 1858. In this he created the part of Lord Dundreary, which became the star part in the play. On Nov. 11, 1861, he produced the comedy at the Haymarket Theatre, London, where it ran for 496 consecutive nights. Sothern's next greatest London success was

the lead in T. W. Robertson's *David Garrick*, 1864. He died Jan. 21, 1881. See Dundreary.

Sothis. Greek form of the ancient Egyptian name of Sirius, the dog-star. Its rising with the sun on July 20, when the Nile inundation began, gave it importance in the Egyptian calendar. As the solar or sothic year comprises nearly 365½ days, and the civil year reckoned 365 days only, the calendar—until Augustus introduced leap year—receded one day every four years, and a sothic period, consisting of 1,460 years, elapsed before the calendar coincided again.

Soto, HERNANDO OR FERNANDO DE (c. 1496-1542). Spanish explorer. He was born at Jeréz de los Caballeros, Estremadura. In 1519 he joined an expedition to Darien, and in 1524 he helped to conquer Nicaragua, afterwards sailing along the coast of Central America. In 1532 he brought reinforcements to Pizarro in Peru, where he took a prominent part in the conquest. Charles V appointing de Soto governor of Cuba and Florida, he sailed thither on an expedition in search of gold in 1539, and for nearly four years explored the country between the Atlantic and the lower Mississippi, crossing that river in 1541, and reaching Arkansas. He died of fever on the banks of the Mississippi in May or June, 1542. *Consuli* Life, R. B. Cunninghame Graham, 1903; De Soto and the Conquistadores, T. Maynard, 1930.

Sou. Obsolete French copper coin, the twentieth part of a livre. It ceased to be coined when the decimal coinage was introduced, but gives its name to the present 5-centime piece.

Soubise. Name of a noble French family. It was allied to the family of Rohan by the marriage of a female representative, Catherine de Parthenay, in 1575. Among its members was Henri, duc de Rohan (*q.v.*). His brother Benjamin (c. 1583-1642) fought under Maurice of Nassau, and was a leading Huguenot. He fought against Louis XIII and fled to England, 1622, afterwards commanding a small fleet against Louis, and aiding Buckingham in his attempt to save La Rochelle. He died in London, Oct. 9, 1642. Charles de Rohan, prince de Soubise (1715-87), fought under Louis XV, 1744-48, was defeated by Frederick II at Rossbach, 1757, and became marshal in 1758. He was a lifelong friend of Louis XV, and with his death, July 4, 1787, the line be-

came extinct. The hôtel Soubise, Paris, acquired by this prince in 1742, was occupied by the national archives after 1808.

Souchez. Village and river of France. The former is in the dept. of Pas-de-Calais, about $4\frac{1}{2}$ m. S.W. of Lens on the Béthune-Arras road and situated between the ridges of Vimy (*q.v.*) and Notre Dame de Lorette. The river, partly canalised, is known as the Deûle in its lower reaches. The Souchez dist. was fiercely contested in the First Great War, and this and other villages were obliterated. It was the centre of severe fighting between the French and Germans, May-July, 1915. In 1922 the village was rebuilt, partly by funds subscribed by the borough of Kensington, London.

Soufflé (Fr. *souffler*, to puff or breathe). Very light dish of eggs and some farinaceous substance, such as flour or potatoes. A soufflé must be served immediately the heat has raised it high above the basin in which it has been cooked, or it will become heavy.

Soul. Mental principle regarded as a personal entity separate from the body, manifested in individual mental life. It is not the mind, but that which thinks and wills. In psychological language, however, it is generally identified with the mind. Theologically, although strictly distinct from spirit, it commonly denotes a simple, immaterial, immortal substance in man, the origin of all his mental operations and desires, whereby he is distinguished from other animals.

Primitive mankind regarded all things in nature as endowed with souls, partaking of the nature of breath or refined substances. This view was subsequently limited to the animal kingdom, although even in recent times souls have been ascribed to plants. It was at first believed that the soul was material, and perished with the body. Plato put forward the idea that it was immaterial, immortal, and tripartite, only temporarily connected with the body. Aristotle assumed three different kinds of soul—the nutrient (the vital principle of plants), the sentient (animal), the thinking (man). The soul was not itself a separate entity.

During the Middle Ages the Platonic and Aristotelian theories, modified in order to reconcile them with Christianity, were equally supported, until Aristotelian monism gave way to the dualism of Descartes. He held body and soul to be essentially different beings, the essence of the one being ex-

tension and of the other thought, whose combination in man was due to divine assistance. Locke assumed the soul to be a sheet of blank paper ready to receive sensations. Leibniz explained the reciprocal action of soul and body by the theory of pre-established harmony (*q.v.*). Soul and body for him were like two clocks, originally set together and moving at the same rate.

Spinoza and some later thinkers regard the soul not as an independent entity, but as a modification of the infinite, all-embracing cause of the world. On the other hand, the empiricists (Hume, Mill) deny that there is anything real corresponding to the soul, nothing but the immediately given manifold of successive states of consciousness. It has been assumed that internal experiences (emotions, impulses) are to be referred to a real subject which lies at the bottom of them, as external phenomena are referred to matter, and that the unity of consciousness amidst its manifold content points to a simple substratum as the bearer of this conscious process.

These views, however, are now generally rejected. Soul is thought of not as a thing determined by any qualities, but as the constant inner activity of which we are directly conscious, and which, ever receiving fresh stimuli from external impressions, assists in determining the course of individual internal life. See *Metaphysics*; *Metempsychosis*.

Soulbury, HERWALD RAMSBOTHAM, 1ST BARON (b. 1887). British politician. Born March 6, 1887, and educated at Uppingham and University College, Oxford, he was called to the bar in 1911. As Conservative M.P. for Lancaster, 1929-41, he was minister of pensions, 1936-39; first commissioner of works, 1939-40; then president of the board of education, and from 1941 chairman of the assistance board. As Lord Soulbury he became known for his chairmanship of the committee which fixed a new salary scale for teachers (see *Burnham Scale*). In 1944 he presided over the Ceylon commission, and in 1949 became gov.-gen. of that dominion.

Soult, NICOLAS JEAN DE DIEU, DUKE OF DALMATIA (1769-1851). French soldier. Born at St. Amans-la-Bastide, Tarn, March 29, 1769, he joined the army in the ranks in 1785, and by 1794 had become a brigadier. Service under Masséna in Switzerland and Italy added to his reputation, and in 1804 he

was made a marshal. He took part in the fighting against the

Marshal Soult,
French soldier

Austrians and the Prussians, was present at Austerlitz, Eylau, and other battles, and received his dukedom in 1808. Transferred to Spain, he forced the British to

evacuate Portugal in spite of his defeat by Moore at Corunna. Overrunning the S. of the country, he settled at Oporto, from which he was ousted by Wellington.

Appointed to the chief command in Spain in 1809, Soult fought with varying success, winning a great victory at Ocaña, and occupying Andalusia in 1810, but suffering defeat himself at Albuera, while his lieutenant, Marmont, was worsted at Salamanca. Some disagreement with Joseph Bonaparte then caused Soult to leave Spain, but after fighting in Germany during 1813, he was sent back by Napoleon on receipt of the news of the disastrous battle of Vittoria. In spite of Soult's brilliant generalship and determination, his raw levies were no match for Wellington's veterans, and the defeat of Toulouse laid the way to Paris open to the British.

On the abdication of Napoleon, Soult, whose course was dictated at least as much by ambition as by loyalty, made his peace with the new régime; but he declared again for Napoleon in the Hundred Days' campaign, and went into exile after Waterloo. In 1819 he was permitted to return to Paris. Made a marshal again, and from 1827 a peer, he represented France at the coronation of Victoria, and under Louis Philippe was minister for war, 1830-34 and 1840-44. He formed a short-lived ministry in 1832. He died Nov. 26, 1851. His *Mémoires* were published in 1854.

Sound. Term applied both to the cause and to the sensation of hearing. Sound is caused by vibrations, transmitted by waves through the air, detected by the eardrum of human being or animal, and conveyed as a sensation by the aural nerve to the hearing centres of the brain.

Sounds occur in nature in very great variety and degree of complexity. Experimental examination shows that those which have the simplest character are musical sounds. A simple and regular to-and-fro motion of the air gives the

impression of a single or pure musical note or tone. A tuning fork gives such a note. The process can conveniently be represented as a series of sine waves (*see* Wave), in which the crests stand for the compressions and the troughs for the rarefactions. One complete wave, consisting of a crest plus a trough, constitutes a cycle. The arrival of a crest forces the eardrum inwards; a trough pulls it outwards; the movements of the eardrum correspond exactly with those of *e.g.* the tuning fork. The frequency of the waves is called the number of cycles per second. The frequency of the vibration determines what is called the pitch of the note, *i.e.* its position in the musical scale. A frequency of 256 c.p.s., no matter how produced, always gives rise to the sound called Middle C. Double the frequency, and the sound rises an octave in pitch; halve the frequency, and it falls an octave.

It is necessary to distinguish carefully between the intensity or loudness of a note and its pitch. The same musical note will be heard with different degrees of loudness, according to the range over which the air particles in the ear move to and fro. This range is called the amplitude of the vibration, and if it is large the sound is loud; if small, the sound is feeble; but this will have no effect on the pitch, if the time occupied by each vibration remains unaltered.

The Musical Interval

Two musical notes of different pitch have what is called a musical interval between them. This is defined as the ratio of the frequencies of the notes. If, for example, the frequency of one note is 500 per sec. and that of the other 300 per sec., the musical interval is $\frac{500}{300}$, *i.e.* $\frac{5}{3}$. But the interval would be the same for any other pair of notes, such as 250 and 150 or 5,000 and 3,000, which have the same ratio of frequencies, and the notes would bear the same musical relation to one another. There exists a recognized sequence of eight musical intervals, called the natural musical scale, which forms the basis for the production of music. The numerical relations are simple, and are as follows:

Natural Musical Scale (Major)

Note: *do re mi fa sol la si do'*
Interval: 1 $\frac{9}{8}$ $\frac{5}{4}$ $\frac{4}{3}$ $\frac{3}{2}$ $\frac{5}{3}$ $\frac{2}{1}$ 2.

The significance of this table is that, taking *do* as the standard note, the ratio of the frequency of any other note to that of *do* is given by the fraction indicated.

The eighth note from *do*, *i.e.* *do'*, has twice the frequency of *do*, and is called its octave.

This musical scale is recognized by the ear as the same sequence, whatever may be the actual frequency of *do*. We merely pass from one key to another by altering the frequency of the standard or key note, and the corresponding frequencies of the other notes may be found by multiplying that of the key note by the appropriate interval. In actual practice the intervals between *do-re*, *re-mi*, *fa-sol*, *sol-la*, and *la-si*, are further subdivided, so that the scale consists of thirteen notes, the successive intervals between which are called semi-tones.

Concord and Discord

When two or more musical notes are sounded simultaneously, their combined effect on the ear is pleasant or otherwise. In the former case the notes are said to be concordant, in the latter case discordant. In musical instruments the production of concordant effects is aimed at.

No musical instrument produces a pure note consisting of the fundamental frequency alone; the second, third, and higher harmonics, called overtones, at twice, thrice, etc., the fundamental frequency are always present. It is the balance of the harmonics and the relative amplitude of fundamental, second, third, and higher harmonics that determines the timbre, or individual tone, of any particular instrument. The fundamental is the same when Middle C (or any other note) is played on piano, organ, clarinet, saxophone, cornet, harp, or cello; the harmonics identify instantly the instrument producing the note.

All musical and other pleasing sounds consist of sine waves, or complex combinations of simple sine waves. And the combinations can be exceedingly complex. When, for instance, a full orchestra is playing the ear hears at any instant a sound representing the whole ensemble. The sound wave giving this is a combination of the fundamentals and the harmonics produced by every instrument in action at the moment.

Non-pleasing sounds are the results of the arrival at the eardrum of sound waves which are not combinations of sine wave forms. Such sounds are classed as "noise" and their wave forms are said to be random. Their character is often very complex, but they may still be regarded as equivalent to a mixture of pure notes, only there

are no longer harmonic relations between the constituents.

In general, any body which vibrates with a frequency lying within certain limits (about 16 to 22,000 per sec.) will constitute a source of sound, from which the effects are conveyed to the human ear. The transverse vibration of a violin string, the periodic puffs of air emanating from the apertures of a siren, the whirr of an aeroplane propeller, the buzzing of a bee's wings are examples. For the propagation of sound it is necessary that the source should be in contact with some material medium, for example, the air, as is usual, or water, or even the earth. If the vibrating body is in a vacuum, no acoustic effects proceed from it.

The vibrating body sets in similar vibratory motion the medium next to it, and each successive portion of the medium is acted upon in turn, receiving from its predecessor some portion of the motion, until, ultimately, the observer's ear is reached. This transference of motion takes time, and the disturbance travels through the medium in the form of a wave or pulse with a speed depending on the properties of the medium, but independent of the sound's intensity and character.

The only factor affecting the velocity of sound is the character of the medium through which it is transmitted and the temp. Loudness and the pitch or frequency have little influence. Velocity is least in gases and greatest in solids; is independent of the pressure but increases as the square root of the absolute temp. At 0° C. sound velocity at sea level in still air is 1,087 ft. per sec.; in fresh water, 4,714 ft. per sec.; in sea water, 4,990 ft. per sec.; in wood, 12,620 ft. per sec.; in steel, 16,400 ft. per sec. Increase in velocity due to temp. amounts to approx. 2 ft. per sec. for each degree C. of rise in temp. Thus, the velocity of sound in air at sea level at a temp. of 20° C. would be $1,087 + (2 \times 20) = 1,127$ ft. per sec. Velocity increases with altitude. *See* Ear; Harmony; Hearing; Sound Reproduction.

SOUND REPRODUCTION & AMPLIFICATION

Ralph W. Hallows, M.I.E.E., author of *Wireless Simply Explained*, etc.

The origins and development of methods of recording sound are here described, together with the systems of amplification and reproduction used in apparatus ranging from the gramophone and the dictating machine to the sound-film and the magnetophon. See also Edison, T. A.; Gramophone; Loudspeaker; Microphone; Phonograph; Radio; Telephone; Thermionic Valve

From quite early times man has made use of means of amplifying sound. The principle of the megaphone was well known to many ancient peoples and use of it was made for transmitting orders to bodies of workmen and to troops on the battlefield, and for other purposes as well. There can be little doubt that the priests in charge of the oracles and the talk-statues of Greece and Egypt produced their effects by means of the speaking tube and the megaphone. Greek and Roman theatres were out of doors and often very large. All the actors wore masks, typifying the hero, the villain, the heroine, etc., and these seem to have contained some form of megaphone to amplify their voices.

Early Recording Experiments

Attempts to find a method of causing sound waves to make their own records date back to about 1800. The first successful instrument was Leon Scott's phonautograph. In this the surface of a metal cylinder, revolving on a screw thread, was blackened with fine soot from a smoky flame. As the cylinder moved sideways along the screw thread, a fixed stylus traced a helical line on the treated surface. The stylus was connected to a membrane stretched over one end of a tube. When sounds such as vowels or single syllables were spoken into the other end of the tube the waves set up caused the membrane to vibrate. The stylus made corresponding movements, which were recorded on the drum as perturbations of the normal regular line of the helix. This instrument and others which followed it, such as Barlow's logograph and Wheatstone's flame recorder, were laboratory apparatus and nothing else. Their inventors had only one end in view: the study of sound wave forms. It does not seem to have occurred to them that if sounds can be made to record themselves, it should also be possible to devise means of sound reproduction from such records.

The first man to grasp this and to realize its possibilities in entertainment was Thomas Alva Edison. In his first phonograph (1877) he used a brass cylinder with a helical groove cut into it. Round the

cylinder, tin foil was wrapped tightly. The stylus of Scott's instrument was replaced by a sharp cutter, attached to a membrane stretched over one end of a tube. When no sound reached the open end of the tube the cutter simply pressed the tin foil evenly into the groove. But the arrival of sound waves caused the membrane carrying the cutter to vibrate; the groove thus became filled with foil cut into "hills and dales" corresponding to the amplitude and frequency of the applied sound waves. The louder the sounds and the more vigorous the vibrations produced, the higher were the "hills" and the deeper the "dales." The number of hills and dales made in a given time depended on the applied frequency.

The sounds were reproduced by reversing the recording process. Instead of a sharp-edged cutter, a round-pointed reproducing stylus, attached to a membrane, was made to run in the groove. Every hill in the record caused the reproducing membrane to be pressed in; each dale allowed it to spring outwards. The record therefore compelled the reproducing stylus and membrane to vibrate just as the recording membrane and cutter had vibrated. In Edison's commercial models, sounds were recorded on and reproduced from wax-coated cylinders—a method still used in office recording machines (see "Dictaphone").

The principle of the soundbox used in early phonographs is illustrated in Fig. 1 a. The

stylus, fixed to the middle of the diaphragm, is moved up and down by the hills and dales encountered by its point as it moves along the groove of a cylindrical record.

These movements are communicated to the diaphragm, which is made to vibrate in accordance with the frequencies and amplitudes recorded. Movements of the diaphragm cause compressions and rarefactions of the air in the sound-box chamber, thus setting up sound waves. The soundbox itself is responsible for some degree of mechanical amplification. The surface area of the diaphragm is much greater than that of a cross section of the neck, hence the amplitude of the compressions and decompressions at the neck is greater than at the inner surface of the diaphragm.

The purely mechanical reproduction obtainable by the simplest possible means from the marks cut into a gramophone record can be judged in the following way: Fold a sheet of stiff notepaper into a sharp V and hold the point of the V lightly in the groove of a revolving record. Reproduction of what is on the record is obtained because the paper is made to vibrate. The reproduction is faint and it is "tinny," but in the early days of sound reproduction few were at all critical of the quality, and the horn and soundbox ensured that a considerable volume of sound was produced.

Though Bell invented the telephone, though Edison discovered (without realizing its importance) the principle of the wireless valve, and though the first practical phonographs were a joint Edison-Bell achievement, their instruments were non-electrical. So, too, was the original gramophone, a considerable improvement on the phonograph. In the mechanical gramophone both the recorder and the reproducer had soundboxes with vertical diaphragms (Fig. 1 b). The cutter of the one and the needle holder of the other were connected to the diaphragm through a lever system, the effect of which was to amplify the movement imparted to the diaphragm. The reproducing stylus was replaced by the easily changeable needle: the records, instead of being rather bulky and very fragile wax-coated cylinders, were flat disks. The vertical dia-

phragm meant that the cuts made in the record were no longer of the hill-and-dale type, but were from side to side. But though the gramophone and its disks with side-

to-side, or lateral, recording ousted the phonograph, there is a good deal to be said in favour of the first hill-and-dale, or vertical, method. The gramophone process was still entirely mechanical, but it proved outstandingly successful; millions of records were made and sold, and the gramophone rapidly became a highly popular supplier of domestic entertainment.

The quality of speech and music recording and reproduction was rapidly improved. The mechanically made record, mechanically reproduced, contained no bass and very little of the higher audible sounds, however; and though listeners who had heard nothing better accepted it as pleasurable, for the human ear is amazingly accommodating, to a listener who has heard reproductions by later methods the distortions of mechanical recording and reproduction are obvious and highly disagreeable.

While recording remained mechanical enormous horns were used in the recording studios. Into their mouths vocalists and instrumentalists sang or played; orchestras had to be tightly packed together close to the wide opening of great funnels. The disk-cutting apparatus was in the studio, which had to be kept at a high temp. in order that the surface of the wax should be sufficiently soft. The process of making copies of the records is explained under Gramophone: Record Manufacture.

The application of the thermionic valve to audio frequency in the wireless receiver showed how it affected amplification in electrical copies of sound waves. In 1925, the first electrically made gramophone records became available. Fig. 2 illustrates the principle of (a) mechanical and (b) elec-

The principle of the electro-magnetic pick-up is shown in Fig. 3. The stylus, whose rounded sapphire tip runs in the groove cut in the record, forms the armature of the permanent magnet and the core of the speech coil, which is wound with many turns of fine wire. The rubber suspension of the stylus is so arranged that it is held rigidly fore and aft, but can move freely from side to side. The grooves in the record impart a side-to-side movement to the stylus. This brings about changes in the magnetic lines of force cutting the turns of the coil, with the result that E.M.F.s are induced in its windings. The amplitudes and

Sound. Fig. 3. Simplified diagram showing the principle of the electro-magnetic pick-up

frequencies of such E.M.F.s are in accordance with those of the sound waves which cause the record to be made. Hence, if both record and pick-up were perfect, voltages which were exact electrical copies of the original sound waves would appear across the coil and could be passed on to an amplifier.

The principle of the recorder is similar to that of the pick-up, though here the train of operations is the exact opposite. Fluctuating currents from the microphone are fed after amplification to the windings of the speech coil, causing

The records and reproducing apparatus used in electrical recording on wax disks and electrical reproduction from them are not unduly expensive; and any number of disks can be mass-produced from the master record. On the other hand, wax disks are easily scratched, broken, or distorted in shape by heat. No perfect reproducing stylus has yet been evolved, for all wear away the impressions cut originally in the grooves; reproduction is for that reason a little less good every time a record is replayed.

Limits of Electrical Recording

Both the recorder and the pick-up have mass and therefore inertia; neither cutter nor stylus can exactly reproduce the original sound wave forms. There is a limit to the frequencies which can be recorded and reproduced faithfully. Though sounds audible to the human ear have frequencies between about 16 and 16,000 C.P.S., the range of a commercial wax record is some 50-5,000 C.P.S. Also, when an orchestra is playing in a concert hall the difference in their power output on *pianissimo* and *fortissimo* passages is enormous; but this cannot be faithfully recorded on the disk. The cutter must be given a certain minimum amount of side-to-side movement if it is to produce a master record from which pressings can be made; the cuts in the disk must give rise to movements of the reproducing stylus large enough to cause E.M.F.s which will operate the associated amplifier. Again, the movements of the cutter are limited, for the number of grooves to the inch and therefore the space that any part of any groove can occupy is fixed by the pitch of the lead screw carrying the recording head. The stylus of the pick-up would be liable to jump out of the grooves were they too wide.

It therefore becomes necessary to use contrast compression in making wax records so that, though the conductor may make his orchestra now fall to *ppp* and now swell to *fff*, the wax record of their performance will show a range not much greater than from *p* to *f*. Various methods of "automatic contrast expansion" are used in some reproducers to counteract this; but results are far from perfect.

Numerous other forms of both recorder and pick-up much less simple than those described have been developed with the object of obtaining both a wider

Sound. Fig. 2: a, mechanical and, b, electrical recording

trical recording. For the second, an orchestra can take up its normal space; the temperature of the recording studio can be comfortable, since the disk cutting apparatus is outside it. A small horn suffices to convey the sound waves to the microphone, which converts them into electrical impulses. The valve amplifier provides the required magnification; the electrical recorder re-converts the electrical impulses into vibrations and makes corresponding cuts in the grooves of the wax disk.

changes in the magnetic field and corresponding movements of the armature. To the armature is attached a sharp-edged cutter; as this is driven over the surface of the wax disk it cuts wavy grooves which record all its side to side movements. The cutter produces wax swarf (fine shavings) which must be got rid of as soon as it is made to prevent it from being swept round on the disk and fouling the edge of the cutter. This is usually done by a suction tube attached to the recording head.

range of frequencies and a less limited range of contrasts; but few have been adaptable for ordinary use with commercial pressed records. Moreover the largest record normally available to the average user is the 12-in. disk, playing for about four mins. Both sides of a dozen 12-in. records can be played at a sitting by instruments with automatic record changers; but there is necessarily a short break whilst the changer does its work.

Surface Noise

The phenomenon called needle scratch, or surface noise, associated with the wax disk system has led to much hard work on the part of inventors and research workers in a continuing vain effort to overcome it. Innumerable materials have been tried for the disks and for needles or stylus tips; and filters of various kinds have been tried in the amplifier stages.

The reason for surface noise is this. The movement of the reproducing tip over the surface of the disk gives rise to random wave forms. It is characteristic of such wave forms that they, so to speak, jar circuits (if they are electromagnetic or electrical wave forms) or materials (if they are air wave forms) into vibration at their natural frequency. An illustration of random sound wave effect may be obtained by raising the lid of a piano keyboard an inch or two and letting it fall: every string is set vibrating and gives out its own note under the influence of the random or noise wave from the slamming of the lid. Atmospherics have similar effects on wireless reception. They have random wave forms and they set the aerial oscillating at the frequency to which it is tuned. In disk reproduction the random wave forms due to needle scratch provoke, from any part of the reproducing apparatus which has a resonance of an audible frequency, responses

unpleasant to the ear. Limited success in overcoming the phenomenon has been achieved by designing reproducing apparatus which has no resonances within the audible frequency range.

Once the microphone, the loudspeaker, and their associated amplifiers had reached such a state in which the distortion and the noise due to them were almost negligible, the basic problems of sound recording became (1) to find a means of making electrical copies of sound waves impress themselves faithfully on something; and (2) to discover a way of making these impressed copies give rise in the reproducer to fluctuations of voltage or current corresponding exactly with the original fluctuations in the recording microphone circuit. The utter-wax-disk-pick-up system is one way of doing it; there are several other possible methods. The first to achieve successful exploitation was the sound-track system used in talking films. In the early 1920s—and even before—attempts had been made to synchronise wax disk sound records with the action of ciné films. The insuperable difficulty was that whenever the film broke, repairs shortened it by some inches. Hence even if synchronisation were perfect to start with, it grew rapidly worse and worse (sometimes with ridiculous results) when the film was in use.

Sound track recording consists in converting the electrical fluctuations corresponding to sound waves into fluctuations of light and photographing these on the edge of the film. The principle illustrated in Fig. 4 is that of one of the many systems which have been developed. The output of the microphone amplifier is fed to a mirror galvanometer, the frequency and amplitude of the mirror's movement about its axis corresponding exactly to the variations of the microphone currents produced by the sound waves. As the mirror moves, a greater or smaller amount of light is sent through the slit in the second screen and the image recorded on the film is correspondingly varied. Both variable density and variable area systems are in use. In the former, the track

is of constant width, but varies in shade from pale grey to black. In the latter the shade is constant and the width of the track varies.

For reproduction, use is made of the photo-electric cell, in which currents proportionate to the amount of light reaching the cathode are set up by an applied beam of light. The principle of one system is shown in Fig. 5. The sound track record on the film varies the amount of light reaching

Sound. Fig. 5. Simplified diagram showing method of sound-track reproduction

the photo-electric cell from the fixed source. The currents set up in the photo-cell are therefore copies in both amplitude and frequency of those by which the sound track record was made. They are passed via the amplifier to the loudspeakers in the auditorium.

Sound track recording has many merits. A wide range of audio frequencies can be recorded and reproduced: as nothing in the way of a stylus traverses the surface of the record, there is no needle scratch and no wear, save that due to the bendings of the film on its way through the various sprockets of the reproducer and to the slight injuries which it is bound to incur; synchronisation problems do not arise, since sound and action are recorded on the same film; recordings of any length within reason can be made; the volume compression necessary is less than with the wax disk.

The magnetic method of sound recording and reproduction consists in making sound waves record themselves by producing varying degrees of magnetisation in a steel wire, or in minute particles of magnetite fixed to the surface of a flexible ribbon or tape. Suppose (Fig. 6) that the amplified output of the microphone is applied in the form of considerable variations of current to the windings of an electro-magnet; the result will be the production of a magnetic field varying in strength and frequency in accordance with the sound waves exciting the microphone. If a steel

Sound. Fig. 4. Principle of one method of sound-track recording

tape is passed at uniform speed through this varying field, it will

Sound. Fig. 6. The principle of the steel wire recording system

receive, as it travels from a containing reel to a take-up reel, a permanent magnetisation embodying fluctuations corresponding to those of the original sound waves. Now, rewind the wire and pass it (Fig. 7) through a pick-up coil. The varying magnetic fields caused by different parts of the travelling wire give rise in the coil to corresponding E.M.F.s. These are amplified and passed as current fluctuations to the speech coil of the loudspeaker. The processes of both recording and reproduction are actually more complicated than this simplified ex-

Sound. Fig. 7. Illustrating the principle of reproduction from a magnetised wire

planation which, however, gives a working idea of the steel wire magnetic system.

It has many advantages. The cost of the wire is trifling; records are more or less permanent, but can be erased and the wire used again; continuous recordings of considerable length can be made; even long recordings need little storage space. The drawbacks, however, are serious. The wire is bound to contain a considerable noise, due to terrestrial magnetism and other causes; the range of audio frequencies that can be recorded and reproduced is limited.

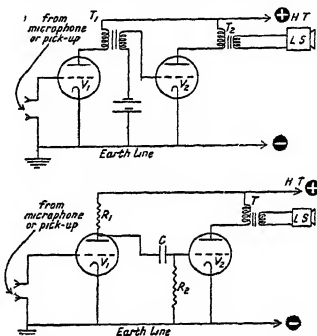

The German magnetophon uses a plastic tape coated with tiny particles of magnetite. Before even a virgin tape passes through the recording head (Fig. 8), it travels through the erasing head, which applies a magnetic field, alternating at supersonic frequency, to each particle. The effect of this field

is to put each particle through its hysteresis curve thousands of times a second and to shake any residual magnetism out of it. The result may be likened to the demagnetisation of a permanent magnet produced by hammering. Whether the tape is used or unused, it leaves the erasing head carrying no record whatever of sound or noise. Whilst passing through the recording head the tape is also subjected to an alternating magnetic field in addition to the fluctuation field which impresses the sound record. The effect of this alternating field may be likened to that of the gentle tapping of a steel bar which so much facilitates its magnetisation when it is being stroked with a permanent magnet. It overcomes the inertia of the particles and renders them much more susceptible to magnetisation by the varying magnetic field of the recording head. In the play-back or reproducing head of the recorder (by which any recording can be monitored), the magnetic fields of the magnetite particles induce currents, which are amplified and passed to the loudspeaker. When the instrument is used purely as a reproducer the erasing and recording heads are, of course, switched out of action.

By the magnetophon principle audio frequencies from some 25 to 12,000 cycles or more a second can be recorded and reproduced with negligible background noise or distortion. The records are permanent (though they can be erased at will and the tape re-used); material costs are not unduly high and storage presents no difficulty. Some form of magnetic tape recording and reproduction may well replace the wax disk for domestic, as well as for other, purposes.

Special precautions have to be taken to minimise distortion caused during amplification by thermionic valves and loudspeakers. The principal types of distortion in amplification are: (1) amplitude distortion, which alters the relative loudness of sounds: harmonic distortion, which means the over-emphasis of certain harmonics of the original sounds, is one form of this; (2) frequency distortion,

which means the upsetting or suppression of the original frequencies; and (3) phase distortion, which means an alteration of the phase relationship of the original sound waves. Of these (1) and (2) are of the greatest importance in sound reproduction. Small, cheap wireless receivers and disk reproducers are great offenders in the matter of frequency distortion, since few of them can deal at all adequately with frequencies below about 75 C.P.S. or above 4,000 C.P.S.

Sound. Fig. 9. Two possible forms of interval coupling in an A.F. amplifier

Fig. 9 shows two possible interval couplings of an A.F. amplifier. At *a* transformer coupling is used; the coupling at *b* is of the resistance-capacitance type. The first is seldom used, partly because A.F. transformers are expensive, bulky, and heavy components, but chiefly because they are bound to introduce an undesirable amount of frequency distortion. Both the primary and the secondary windings of a transformer are inductors, components possessing the quality of inductance. The A.C. equivalent of D.C. resistance in an inductor is reactance, which is not fixed, but varies according to the applied frequency. The higher this frequency, the greater is the reactance of a given inductor and *vice versa*. The voltage developed across the primary of an A.F. transformer and passed on via the secondary to the next valve depends upon the reactance: the higher the reactance, the greater is the voltage drop across the primary. The voltage changes across the primary are considerably greater for the upper audio frequencies than for the lower.

For these reasons, the resistance-capacity coupling of Fig. 9 *b* is more usual for A.F. interval couplings. The resistors R_1 and R_2 do not discriminate be-

Sound. Fig. 8. The principle of tape recorders and reproducers of the magnetophon type

tween high and low frequencies: whatever the frequency the voltage developed across them would seem to be unaffected. But the circuit contains certain capacitances. One of these is visible in the capacitor C in Fig. 9 *b*; other capacitances, though present, are invisible. Amongst these is the output capacitance (anode-cathode) of V_1 . Like an inductor, a capacitor presents reactance; but in this case the higher the frequency, the less the reactance and *vice versa* for a given capacitance. The apparently simple circuit of Fig. 9 is, of course, in practice a very complex one. The "real" circuit is shown in the simplified equivalent form of Fig. 10. The +H.T. line, though at

Sound. Fig. 10. Simplified equivalent of the Fig. 9 circuit. R_1 , R_2 , and C as in Fig. 9. COV_1 = output capacity of V_1 .

high potential with respect to the earth line from the D.C. point of view, is at earth potential so far as A.F.s are concerned.

The invisible output capacitance of V_1 , which is in parallel with R_1 , acts almost as a short circuit path for the higher frequencies. The potentials delivered to the grid of V_2 are those developed across R_2 . The reactance of C and the resistance of R_2 are in series, and since the reactance of C varies according to the frequency, it may be represented, as in Fig. 11, by a variable resistor. This and R_2

Sound. Fig. 11. Fig. 10 may be redrawn as above to indicate the effect of the varying reactance of C

form a potential divider; the greater the potential drop across C , the smaller that across R and therefore the smaller the potential changes delivered to the grid of V_2 . The reactance of C and the potential drop across it are large for low A.F.s and small for high A.F.s. Hence the combination of COV_1 and R_1 is liable to introduce frequency distortion by poor response to the upper A.F.s, whilst that of C and R_2 has a similar effect on the lower A.F.s. Minimisation of such distortion is by no means simple.

Triodes used in either of the Fig. 9 circuits cause second har-

monic distortion, which is a form of amplitude distortion and means that undue prominence is given to the second harmonics of sounds. This is due to the fact that the so-called straight portion of triode characteristics is really not straight, but slightly curved; the effect when the valve is working is that one half of each cycle receives more amplification than the other. Second harmonic distortion can be minimised by careful choice of R_1 in Fig. 9 *b* circuit; it can be virtually eliminated by using triodes as "push-pull" amplifiers.

Some of the frequency distortion inherent in the Fig. 9 *b* circuit may be greatly reduced by substituting pentodes for triodes, for with these valves the stray capacitances are very much smaller. But harmonic distortion is likely to be more in evidence. This time it is third harmonic, which is far more unpleasant to the ear than second and cannot be got rid of by using valves in push-pull.

Sound. Fig. 12. The heavy lines indicate a method of applying negative feedback to the output pentode valve of an amplifier

The most effective remedy is the use of negative feedback (Fig. 12) which may be described as the reverse of reaction. In a reaction or positive feedback circuit E.M.F.s from the anode are fed back in phase with those of the grid circuit; exactly the opposite is the case with negative feedback. The effect is to minimise harmonic distortion, though the gain of the amplifier is greatly reduced.

The type of loudspeaker in general use is the moving-coil instrument, in which the inward and outward movements of a light cone set up sound waves in the surrounding air. No loudspeaker is without its resonances, which means that it emphasises some frequencies more than others. The cone must have mass and therefore inertia, with the result

that there is a falling off in the response at high A.F.s. Sound waves from a cone with a to-

Sound. Fig. 13. In the concert halls sounds reach the ear of the listener (both directly and by reflection from walls and ceilings) from many directions (a). Sounds from the loudspeaker are projected (b) as a beam from a single point

and-fro piston action form a kind of beam (Fig. 13); those listening intently to radio or gramophone reproduction tend to look fixedly at the source of this beam, the loudspeaker. The fact that the source of sound is, so to speak, a point rather than an area tends to make reproduction somewhat unrealistic, particularly when an orchestra is playing. Unsuccessful attempts have been made to remedy this defect and to produce "stereophonic" reproduction.

The beam of sound waves from the cone is of a peculiar kind. The waves due to the highest reproduced A.F.s travel outwards (Fig. 14) in a direction almost in a line with the movement of the cone; the lower the frequency the more are the waves dispersed. Waves corresponding to the lower A.F.s would travel round to the back of the cone, with the result

Sound. Fig. 14. Diagrammatic representation of the selective nature of the beam of sound waves from the cone of the loudspeaker. Those of the highest A.F.s reproduced travel almost straight outwards. The lower the frequency, the greater is the tendency of the wave paths to bend round towards the back of the cone. Were it not for the stop imposed by the baffle board, no bass would be reproduced, since "crests" from the front of the cone, corresponding to the lowest A.F.s, would travel round in time to cancel out the "troughs" on the back of it

that the "pushes" in front would cancel out the "pulls" behind, were it not for the interposition of a baffle board. If a radio receiver is removed from its cabinet, it reproduces hardly any bass at all and reproduction is on this account thin and tinny. The larger (within reason) the baffle board, the better the reproduction of the lower A.F.s. For that reason the console type of receiver, with its larger baffle, gives better quality reproduction than the small table model.

Sound. THE. Strait between Denmark and Sweden. It lies between the island of Zealand and Scania and is 30 m. in length, with a breadth of 3 m. at its narrowest, between Elsinore and Helsingborg, and 37 m. at its widest. It leads from the Baltic Sea N.W. to the Kattegat and has a depth of 20 to 120 ft.

Soundboard. Part of a musical instrument that is intended to reinforce the tone of the strings, which would otherwise be too weak to be effective. In string instruments it is called the belly, and is pierced by sound holes. In the pianoforte it is a plate of wood at the back or the bottom of the instrument, according as it is an upright or a grand. The vibrations of the wood, which are molecular, not transverse, respond to the impulse given by the strings.

The soundboard of an organ has a different object. It is the upper table of the wind chest, and is pierced with holes into which the feet of the pipes are set—as many holes as there are departments in the organ. See Organ.

Sounding. Term which refers to the determination of the depth of the ocean or a river bed. The time-honoured method was to drop overboard a lead weight attached to a line, but this is a slow process and impossible with a fast vessel. An echo-sounding method has been developed, which depends on determining the time interval, t , between sending out a sound at the water surface and receiving the signal reflected back from the ocean bed. The depth, d , is then given by $d = \frac{1}{2} vt$, where v is the velocity of sound in water. Most modern equipment records a profile of the sea bed, from which the depth can be read off directly. See Echo Sounding.

Soup. Liquid food, prepared by boiling meat or vegetables in stock. There are three classes of soup, clear soup or consommé, thick soup, and purée. The foundation of all is known as stock,

the best of which is made from fresh meat and vegetables, with various seasonings, but bones and cooked meat are also used. Fish stock is made by boiling the trimmings of fish.

Clear soup is formed by reboiling the stock with a piece of good meat, the white and shell of an egg, and a lump of sugar, and straining it before serving. A broth is unclarified clear soup, the meat being often served with it. Thick soups have starchy material, such as peas, rice, and carrots, mixed in them, or cream and white of egg. All the ingredients of a purée are passed, when well boiled, through a sieve, and served in the soup. Soup is valuable as an appetiser, although some kinds are also highly nutritious. See Broth; Julienne, etc.

Souris. Two rivers of Canada.

(1) An affluent of the Assiniboine, which it joins at Milford, after flowing for its middle course in the U.S.A.; it gives access to the Missouri valley from Canada. It rises in the Dirt Hills of S. Saskatchewan. (2) Small stream in Prince Edward Island, which flows into Colville Bay on the E. coast; near its mouth is the small town of Souris, which has a lobster packing industry.

Sousa, JOHN PHILIP (1856–1932). American bandmaster and composer. Born at Washington, D.C., Nov. 6, 1856, he conducted for theatrical tours before becom-

John P. Sousa, American composer

ing leader of the U.S. marine corps band, 1880–92. He was world-famous as conductor of his own band, which toured in Europe several times, 1900–05, and round the world, 1910–11. Though Sousa composed many comic operas, he is best known by his stirring military marches, e.g. Washington Post, Semper Fidelis, and Hands Across the Sea. He died March 6, 1932.

South. One of the cardinal points. If an observer in the N. hemisphere turns towards the sun, when the latter attains its maximum altitude for the day, he is facing S. The magnetic declination of a place must be known before true south can be determined with a compass.

South, ROBERT (1634–1716). English divine. Born in Hackney, he was educated at Westminster school and Christ Church, Oxford. In 1658 he was ordained, and he became public orator to the university in 1660. In 1670 he was made canon of Christ Church, holding also the living of Islip. He died July 8, 1716. South won fame as a controversialist, but still more by his sermons, which were long regarded as models.

THE UNION OF SOUTH AFRICA

A. Keppel-Jones, Senior Lecturer in History, Witwatersrand Univ.

This article describes the physical features, communications, people, etc., of South Africa, and the history and form of government of the country since the Union was established in 1910. For earlier history of the area see under Cape Province; Natal; Orange Free State; Transvaal. See also under South-West Africa, and in N.V.

The Union of South Africa occupies the southern extremity of Africa, lying between lat. 22° S. and 35° S. and long. 16° E. and 33° E., almost wholly in the south temperate zone.

South Africa arms

full sovereignty in both internal and external affairs.

The interior of the country is a high plateau, about 40 p.c. of the whole surface lying above 4,000 ft. This plateau is bounded on the E. and S. by the escarpment of the Drakensberg, the principal mt. range of the country, and the

ranges which continue it to the S. and W. Parallel to the latter and to the S. coast run the Zwartberg and Langeberg ranges, which divide plateaux at lower levels, the coastal plain lying in turn below the Langeberg. Farther E. the descent from the Drakensberg to the coast is more regular. The rivers running E. from the Drakensberg watershed are short, the country they traverse is well watered. The Union's longest river, the Orange, and its tributaries run W. to the Atlantic through drier country.

CLIMATE. The mean summer temps. over most of the country range from 60° to 80°, and the mean winter temps. from 40° to 60° F.; temps. are no higher in most of the N. areas than on the S. coast, as the greater altitude compensates for the lower latitude.

On the high plateaux there is a great variation in daily temp., the nights being cool at all seasons. The rainfall exceeds 25 ins. over about one-quarter of the country; this quarter comprises the E. Transvaal, N.E. Orange Free State, Natal, the extreme E. and the S. coast of the Cape Province. There the fall varies from 25 ins. to 50 ins., and in places exceeds 70 ins. Westward the country

the more densely wooded country called bushveld. In the Natal coastal belt there is a narrow fringe of dense sub-tropical bush. The central and N.W. parts of the Cape Province are dry, the vegetation ranging from the sparse stunted bushes of the Karroo to the true desert of the Namaqualand coast. The Cape region, comprising the coastal belt and the adjoining mts. from St. Helena

does not own. The administration's road motor service covers 18,000 m. S. African airways link the principal centres of the Union, and (in cooperation with B.O.A.C.) the Union with central and N. Africa and with the U.K. Private companies operate local air services.

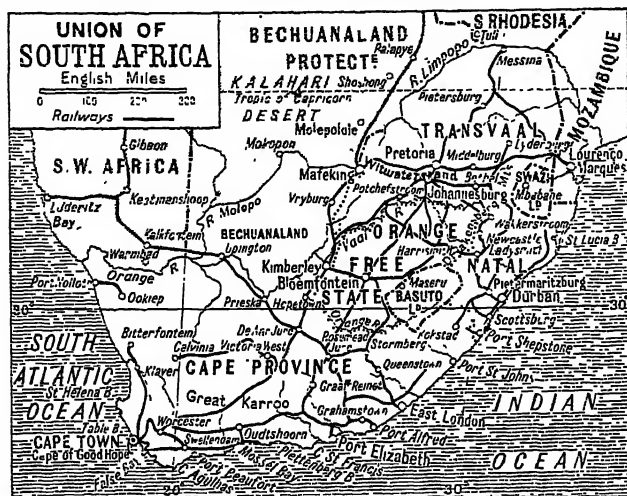

Roads are maintained by the provincial administrations and local authorities, but the National Roads Act, 1935, provided for a system of more than 5,000 m. of national roads, planned by a central board and supported by central funds. The Union has no navigable rivers.

CITIES AND TOWNS. There are nine principal urban centres in the Union. The Witwatersrand is an agglomeration of towns which represent the greatest concentration of pop. in the country. They are Johannesburg (pop., 1946, 727,943), Germiston (128,971), Springs (106,016), Brakpan (83,242), Benoni (74,123), Roodepoort (72,034), Krugersdorp (71,631), Boksburg (53,419), Randfontein (32,323), and Nigel (30,275). The other principal cities are the legislative capital Cape Town (454,052), the administrative capital Pretoria (236,367), Durban (357,304), Port Elizabeth (146,231), Bloemfontein (82,322), East London (78,530), Pietermaritzburg (63,162), and Kimberley (55,645).

RESOURCES AND INDUSTRY. The Union is very rich in gold, coal, and diamonds, and has notable deposits of copper, asbestos, tin, silver, platinum, manganese, chrome, iron. Most of this mineral wealth is in the Transvaal. Ores from which uranium can be extracted are obtained from the Witwatersrand gold mines and the Gordonia dist. of Cape Province; the production of uranium is controlled by the govt.

The principal farm crops are maize (chief area, N. Orange Free State and S. Transvaal), grapes, wine, and deciduous fruit (S.W. Cape Province), citrus fruit (Transvaal bushveld, Natal, E. Cape Province), sugar cane (Natal coast), wheat and other winter cereals (S.W. Cape Province), tobacco (parts of the Transvaal and S. and S.W. Cape Province), and vegetables. Pastoral products, which contribute slightly more in total value than arable, are meat, wool, dairy products, mohair, and skins. S. Africa ranks fifth in world wool production.

Manufacturing industry was greatly encouraged by the two

South Africa. Map of the four provinces forming the Union

becomes drier, the rainfall being less than 5 ins. in parts of the Karroo and Namaqualand. A belt down the W. coast, about 150 m. wide, constitutes the winter rainfall area, where more than two-thirds of the rain falls in the winter months; but only in the S. part of this belt is the rainfall significant. Over most of the rest of the country more than two-thirds falls in summer. Snow falls every winter on the higher mts., rarely elsewhere. Violent hailstorms are a feature of the summer.

VEGETATION AND FAUNA. The characteristic vegetation in the S. Transvaal, most of the Orange Free State, and a belt E. of the Drakensberg extending from N. Natal to the neighbourhood of Port Elizabeth, is tall grass, green in summer and brown, dry and dusty in winter. Below the Drakensberg patches of bush and trees are interspersed with open grass country, and savanna is found also on the N. and W. fringes of this area; for the rest the grassveld is treeless.

The N.W., N., and E. Transvaal pass from open grass country through park-like savanna to

Bay to Port Elizabeth, is a country of short, dark-green, leathery-leaved bushes and shrubs, and very rich in wild flowers. Forest, as distinct from bush, is rare in S. Africa; the most notable forests are in the Knysna district, the Amatola mts., and at Woodbush in N. Transvaal.

S. Africa has been noted for the abundance and variety of its wild fauna. Some of this is still widely distributed, but most of the game is now concentrated in the reserves where it is protected, notably the Kruger national park in the E. Transvaal. Lion, elephant, buffalo, giraffe, many varieties of antelope, and smaller game exist there in natural conditions.

COMMUNICATIONS. The rlys., harbours, and chief airways are state-owned and operated by the S. African rlys. and harbours administration. The rly. route mileage owned and operated within the Union is 11,788; to this should be added the rlys. of S.W. Africa, which were amalgamated with the Union system in 1922, and the main line through Bechuanaland to Bulawayo, which the S.A.R. and H. operates but

Great Wars. By 1941 this activity was contributing 18 p.c. of the national income, second only to mining. Food, drink, and tobacco constitute the largest industrial group, with metal and engineering second. Other important manufactures are clothing and textiles, leather, chemicals, explosives, furniture, building materials, printing, motor vehicle assembly, and wagon building.

The Union's principal imports are clothing and textiles, motor vehicles, locomotives, machinery, hardware, petroleum products, foodstuffs, chemicals, leather and rubber goods, timber, paper. The chief exports are gold, wool, diamonds, fruit and jam, sugar, hides and skins, coal, wattle bark and extract, asbestos. The chief sources of imports are the U.K. and the U.S.A., which are also the principal markets for S. African exports. In 1945 the U.K. provided 32.2 p.c. imports and received 26.5 p.c. of the exports.

POPULATION. The people of S. Africa comprise four chief groups, European, African (commonly called native), Coloured, and Asiatic. The African group consists of the dark-skinned, indigenous peoples speaking Bantu languages. The Coloured are people of mixed blood including European, Bantu and Negro, Hottentot and Malay elements in various proportions. But for census purposes the pure Hottentot and Bushmen races, which survive in small numbers, are included under this heading. The Asiatics are almost all Indians, though there is a small number of Chinese. The Europeans are the descendants of various groups of European colonists. Those who came in the 17th and 18th cents. were predominantly Dutch, but included large German and French elements that were assimilated by the Dutch. Settlers from the British Isles came in the 19th and 20th cents., and there have been smaller numbers from other European countries. The earlier, mainly Dutch group, has evolved a distinct nationality (*Afrikaner*) and language (*Afrikaans*). Owing to intermarriage and the absorption of individuals of one European group by the other, it is impossible now to classify the European population in terms of origin or descent. The only classification is by language. About 56 p.c. of the Europeans are Afrikaans-speaking, 40 p.c. English-speaking, and 1.6 p.c. use both languages equally.

The proportions of one group to another (*see table*) remain fairly constant. Although the

with the house of assembly, or within 120 days of the dissolution of the house if this has led to a

SOUTH AFRICA ; DISTRIBUTION OF POPULATION, 1946

PROVINCE	EUROPEANS	AFRICANS	COLOURED	ASIATICS	TOTAL
Cape ..	859,611	2,327,099	813,190	16,901	4,016,801
Natal ..	232,923	1,699,068	22,623	228,119	2,182,733
Transvaal	1,041,835	3,049,169	55,270	37,503	4,183,779
Orange Free State ..	201,091	660,473	13,967	14	875,545
UNION ..	2,335,460	7,735,809	905,050	282,539	11,258,858

percentage of Europeans in the total pop., which was 21.6 in 1904, had fallen to 20.7 in 1946, the difference is at least partly explained by the incomplete enumeration of non-Europeans in the earlier census.

Of the European pop. in 1936, about 88 p.c. were Protestant, 4.6 p.c. R.C., and 4.5 p.c. Jewish. Of the Coloured people 4.6 p.c. were Mahomedan, 4.7 p.c. R.C., and the rest Protestant. Of the Asiatics 73 p.c. were Hindu, 19 p.c. Mahomedan, and most of the remainder Christian. For the Africans the figures were: heathen, 50 p.c.; European Protestant Churches, 29 p.c.; Native Separatist Churches, 16 p.c.; R.C., 3 p.c.

ADMINISTRATION. The Union consists of four provinces (Cape Province, Natal, Orange Free State, and Transvaal) which united in 1910. At the head of the govt. is a governor-general, representing the king and appointed by him on the advice of his S. African ministers. The prime minister and 11 other ministers forming the cabinet must be members of one of the houses of parliament, to which the cabinet is responsible.

The lower house of parliament, the house of assembly, consists of 159 members, of whom three represent the natives, and six S.W. Africa. The rest are elected by the European pop. (on universal adult suffrage, male and female) and a restricted Coloured electorate in the Cape Province, in single-member constituencies, which are re-delimited every five years by a commission of judges. The upper house, or senate, consists of 48 members. Of these each prov. elects eight, the electoral body consisting of the provincial councillors and the members of the house of assembly for the prov., voting by proportional representation; S.W. Africa sends four (two nominated, two elected). The gov.-gen. appoints another eight, and four are elected by the natives. The senate is elected for 10 years, but may be dissolved simultaneously

change of govt. Disagreements between the two houses are resolved by a simple majority at a joint sitting.

Each prov. has a provincial council, elected by the same voters and representing the same constituencies as the house of assembly, except that the number of constituencies must be at least 25; this is the number in Natal and the Orange Free State, which have fewer members in the house of assembly. The administrator, appointed by the central govt. for five years, is the head of the executive, and is assisted by an executive committee of four elected by the council. Provincial ordinances must be approved by the governor-general-in-council, and must not be in conflict with a Union statute. They deal principally with education (other than university education), hospitals, roads, and local govt.

Legal Jurisdiction

The supreme court consists of an appellate division, sitting in Bloemfontein, and seven provincial or local divisions. Judges hold their commissions, as in the U.K., during good behaviour; the common law of the Union is the Roman-Dutch. The lower courts are those of the magistrates, who are civil servants; the country is divided into magisterial districts for this and various administrative purposes.

Defence is entrusted to the Union defence force, of which the S. African air force and naval forces are branches. There is compulsory part-time training, in principle, for all white male citizens from the age of 17. The civil service is a professional and non-political body, in which appointments, promotions, and discipline are controlled by an independent public service commission of three members.

In many respects the Africans are subject to a separate administrative organization under the dept. of native affairs. Special courts administer native law.

Certain areas are reserves in which no non-African may hold land, and in some of these the tribal chiefs retain certain powers. Many of the laws of the Union discriminate between different groups of the pop., and some persons are therefore subject to controls from which others are free (e.g. pass laws apply to Africans, and prohibition of inter-provincial migration applies to Asiatics).

EDUCATION. Primary and secondary education, which are controlled by the provs., are free for Europeans, and compulsory up to the age of 16 or to standard VI or VIII, according to the prov. There are, however, many private schools at which fees are paid. For the non-Europeans education is neither compulsory nor free, except for Coloured children in the Cape Province. It is provided chiefly by missionary and other private bodies, with state assistance. A start has been made with state schools for non-Europeans.

Universities and Newspapers

Universities are under the supervision of the Union dept. of education. There are five teaching universities—Cape Town, Stellenbosch, the Witwatersrand, Pretoria, and Natal, of which the second and fourth use Afrikaans as the teaching medium, and the others English. The federal university of South Africa, of which the last three in the above list were formerly colleges, still includes four university colleges—Rhodes (Grahamstown), Orange Free State (Bloemfontein), Potchefstroom, and Huguenot (Wellington).

PRESS. Of the English daily journals four (Cape Argus, Cape Town; Star, Johannesburg; Daily News, Durban; Diamond Fields Advertiser, Kimberley) constitute the only considerable newspaper chain in the Union. Other important daily papers are the Cape Times (Cape Town), Natal Mercury (Durban), Rand Daily Mail (Johannesburg). All the English dailies are politically independent but support the United party. The Afrikaans journals are more closely controlled by political parties. The chief are National Party: Burger (Cape Town), Transvaler (Johannesburg), Volksblad (Bloemfontein); Afrikaner Party: Vaderland (Johannesburg); United Party: Suiderstem (Cape Town), Volkstem (Pretoria). There is also a considerable number of Sunday papers, weekly journals of opinion, and popular magazines.

HISTORY. From 1910, when the Union of S. Africa came into

being, to 1948 three men, former leaders of the Boers in the war of 1899–1902 (Generals Botha, Smuts, and Hertzog), held the premiership of the Union. During that time the only attempt to break away from the British Empire came soon after the outbreak of the First Great War, when a small group of Boers, including De Wet, Beyers, and Delarey, planned to overthrow the existing govt. Delarey was killed Sept. 15 by a shot from a police patrol while he was travelling in a car from Johannesburg. De Wet seized Heilbron; Beyers raised a small force in the Transvaal. Botha took the field at once and put Beyers and his force to fight near Pretoria. By the end of Nov. it had virtually ceased to exist. De Wet, his force having also been scattered by Botha, surrendered on Dec. 1, and the rising was at an end.

The Botha govt. of 1910 and its successors under Smuts in 1919–24 were supported by the S. African party, which aimed primarily at drawing the two white groups together and drew support from both. The Unionist party, which was purely British, was absorbed by the S.A.P. in 1921. Many Afrikaners felt that their national aspirations were not satisfied by the S.A.P., and under the leadership of Hertzog seceded from it in 1912, forming the National party. In addition there was a small Labour party with its main strength on the Rand. The participation of the Union in the First Great War on Great Britain's side gave great impetus to the former, and the suppression of the 1922 Rand strike impetus to the latter. They made an electoral pact, were successful at the 1924 elections, and formed a coalition govt. under Hertzog.

This government was shaken by the world economic crisis in 1932, and in the following year Smuts, with a view to obliterating old political distinctions, entered a new coalition under Hertzog. This led to a fusion of the two main parties in the United party. Hertzog's successive govts. aimed at the recognition of S. Africa's sovereign independence (obtained by the Statute of Westminster, 1931) and the establishment of relations between the groups of the pop. on a basis that secured domination to the Europeans. This policy was embodied in a series of Acts in 1936, providing for the separate political representation of the Africans (as outlined

above) and for the segregation of non-European groups in respect of land-ownership.

In each of the old parties there was a wing which refused to accept the fusion of 1933–34. These became the "purified" National party (under Dr. D. F. Malan) and the Dominion party (under Col. Stallard). On the outbreak of war in Sept., 1939, Hertzog proposed neutrality, Smuts rejected it, and the cabinet split. A majority in parliament supported Smuts, who formed a new govt., and whose supporters retained the name of the United party. Hertzog's followers seceded, and most went over to the now "Reunited" National party of Malan. Hertzog himself and a few whose advocacy of equal rights for the English-speaking section was opposed by the Nationalists formed the Afrikaner party.

The Second Great War

Under the Smuts govt. the Union played its part in the Second Great War, sending divs. to E. and N. Africa and to Italy. A total of 345,049 men and women, all volunteers, served in the S.A. forces, many on home defence only; 6,840 were killed. The S.A. 1st div. fought with distinction at Alamein; and the S.A. 6th armoured div., at times with the 8th army, at times with the 5th, was the spearhead of innumerable Allied advances in Italy. After the war, at elections held in May, 1948, a Nationalist-Afrikaner party coalition was successful in obtaining a small majority, and Dr. Malan became premier. See N.V.

South Africa, UNIVERSITY OF. Educational body founded in 1918. Its headquarters are at Pretoria.

and it took the place of the university of the Cape of Good Hope. A federal university, it comprises four university colleges: Orange Free State, at Bloemfontein; Huguenot, at Wellington; Rhodes, at Grahamstown; and Potchefstroom. The university had 86 professors and 3,185 students in 1945. Other universities in South Africa are those of Cape Town, Stellenbosch, Witwatersrand, Natal, and Pretoria.

South African Air Force. Body founded in 1920, which is a branch of the S. African permanent force, being administered by the department of defence. At the beginning of the Second Great War the S.A.A.F. consisted of one squadron and a total of 1,500 men; by the end of the war, in which it served mainly in the Western Desert and the Mediterranean, it had a total of 34 active squadrons.

South African War. Struggle between Great Britain and the Boer republics of the Transvaal and the Orange Free State, Oct., 1899, to May, 1902. Great Britain had, by treaty, the right of controlling the external affairs of the Transvaal and, moreover, had an interest in the affairs of the white population that had been attracted thither by the discovery of gold. The Boer government refused to give civic rights to these men, and in 1899 there were protracted negotiations on these and other points in dispute. No agreement had been reached when, on Oct. 8, the Boers issued an ultimatum, demanding the withdrawal of the British troops who had been sent or were on the way to South Africa. This was treated as a declaration of war.

The Boers at once invaded Natal, and there the first engagements took place. The Boer artillery was surprisingly good and their tactics by no means despicable, but the British regulars, about 4,000 in number, were excellent soldiers, and both sides could claim successes. At Talana Hill and Elandslaagte the British were victorious, but they met with a disaster at Nicholson's Nek. Before the end of Oct., Sir George White, the commander, and his small force were closely shut up in Ladysmith, around which was an increasing army of Boers, while others invested British garrisons in Mafeking and Kimberley. In Nov. a British army gathered at Cape Town and was ready to move forward. Sir Redvers Buller led the largest contingent to the relief

of Ladysmith; Lord Methuen with the Guards and Highlanders set out for Kimberley, while between the two was Gen. Gatacre. All met with defeat.

Methuen came into action first. After two skirmishes, Belmont and Graspan, he reached the banks of the Modder on Nov. 27. Across it the Boers were in strength, but the British compelled the enemy to vacate their positions among the hills. Proceeding farther, Methuen delivered a night attack on some strong Boer lines at Magersfontein on Dec. 11-12. This was a total failure. On the previous day Gatacre's force had met with a reverse at Stormberg.

The hopes of Britain were by this time centred on Buller. Having reached the Tugela, he attacked at Colenso on Dec. 15. The strength of the Boer positions, and the military skill of their defenders, were underrated, and the result was a loss of 1,000 men and, much more serious, a blow to British prestige. It was a slight set-off when in Jan., 1900, a severe attack on Ladysmith was beaten back. By this time Lords Roberts and Kitchener were on the way to S. Africa. Meanwhile Buller failed again at Spion Kop, Jan. 22.

Roberts sent French with a mounted force to relieve Kimberley, and the town was entered on Feb. 15. This prepared the way for the main move against the Boer forces. Their retreat was cut off and they found refuge in the dry bed of the Modder. Then took place the battle of Paardeberg, Feb. 27, which ended in the surrender of 4,000 Boer fighting men. Buller by this time was able to renew his attacks on the Tugela positions. After heavy fighting, on Feb. 28 his army joined hands with the defenders of Ladysmith.

Bloemfontein and Pretoria

Roberts lost no time in following up his successes. Having crossed the Orange, he received the surrender of Bloemfontein on March 13, while an appeal for peace showed that the Boers grasped the realities of the situation. For six weeks the British remained at Bloemfontein, preparing for a further advance by clearing the enemy from the neighbourhood and making safer the rly. line to Cape Town. In these weeks Christian De Wet showed his skill; his chief successes were perhaps at Sanna's Post and Reddersburg.

On May 3 all was made ready for another forward move. On June 5 Roberts entered Pretoria, freeing 3,000 prisoners. Mafeking

had been relieved on May 17, and Buller had cleared the Boers from Natal, thus opening up a converging line of attack on the Transvaal. From Pretoria Roberts moved E. to Komati Poort. Then Lydenburg and Barberton fell, leaving the Boers almost without a stronghold. In Sept. the Transvaal was formally annexed, and in Dec. Roberts left the completion of the task to Kitchener.

During the African summer the Boer cause revived. De Wet as usual was busy, and generally successful in his raids in the Orange Free State, as was Botha in the Transvaal, while the area of warfare spread again to Cape Colony. Mounted men were sent out from England and a number of flying columns organized. Kitchener's plan was to clear the worst areas of their inhabitants, gathering the women and children into so-called "concentration" camps, and to hunt down the fighting men.

End of the Campaign

Kitchener's organization steadily improved. His rlys. became safer and better, and his mounted men more numerous and expert. He ringed round the foe with a chain of blockhouses and completed arrangements for operating away from the lines of rly. This was proved when overtures for peace, which were rejected, came in July, 1901, from the Boers. Encounters continued through the year, and early in 1902 the Boers captured Methuen at Tweebosch, but in March they asked unconditionally for peace. The treaty of Vereeniging was signed at Pretoria on May 31, 1902.

The British troops had increased until the fighting force must have numbered 250,000. The losses were 5,774 killed and 22,829 wounded, while over 20,000 died of disease. The Boers may have numbered altogether 95,000, and the killed about 4,000. At the end 40,000 Boers were prisoners of war. In Jan., 1902, there were 121,965 Boers in the concentration camps. See Botha; De Wet; Kitchener; Ladysmith; Paardeberg; Spion Kop, etc.

Southall. Borough of Middlesex, England. It is about 12 m. W. of London, with a station on the Western region of British Railways, and served also by the Grand Union Canal. Incorporated as a borough in 1936, it returns one

Southall, Middlesex. The bridge built by Brunel which carries a road and canal over the railway

members to parliament. It developed as an industrial centre from 1880, and after the First Great War rapidly increased in area. The chief building is the parish church of Norwood Green, partly Early English. A remarkable bridge by Brunel carries the road over the canal and the latter over the rly. The Brent defines part of the borough boundary. Pop. est. 57,000.

South America. The South American continent, forming the S. part of the land of the W. hemisphere. It is a distinct land mass, surrounded by sea except where the Isthmus of Panama, now pierced by a canal, joins it to N. America. The continent extends through every habitable latitude from 12° N. to 56° S. Its total length from Cape Gallenas in Columbia to Cape Horn in Tierra del Fuego is about 4,500 m. Max. width, from Cape San Roque to Cape Parina, is about 3,200. Total area is approx. 7,000,000 sq. m., with a pop. estimated at 90,000,000. About half the continent is occupied by Brazil. The other countries are Colombia, Venezuela, British and French Guiana, Surinam, Ecuador, Peru, Bolivia, Chile, Paraguay, Uruguay, and Argentina. The pop. of the continent is compounded of European (mainly Iberian), African, and indigenous Indian elements. People of pure European ancestry are not in the majority, yet European influence and character are predominant, and a civilization of a decidedly Latin type, modified by local influences, has evolved. In the remote interior, much of which remains unexplored, there still lurk many tribes of savages with primitive customs and languages. Their number is unknown.

Physically S. America is broadly divided into the region of mountains (Andes), the region of tropical forests (Amazon river), and the region of open plains (Argentina and Patagonia). The great Brazilian plateau is another not-

able element in its configuration. The Andes form a backbone stretching for 4,500 m. The three great river systems are the Orinoco, the Amazon, and the Paraná. For further details, physical, climatic, and historical, see under the various countries.

See also America; Latin America; Patagonia; and map facing p. 7676.

Southampton. Co. and mun. bor., county of itself, and seaport of Hampshire, England. It is 79 m. S.W. of London by rly., having several stations, and stands on a peninsula between the mouths of the Itchen and the Test at the head of Southampton Water. It was made a co. bor. in 1888, has elected two M.P.s since 1295, and has a suffragan bishopric in the diocese of Winchester. Pop. est. 170,360.

Southampton was destined to be a great port by reason of a deep, sheltered estuary, the phenomenon of double tides, and above all its position in the centre of the S. coast. The harbour developed from the efforts of a company which in 1836 purchased 216 acres of mudland near the Town Quay. Enlargements to the docks in the 19th century were carried out partly by rly. companies; in 1927-34 there was another big extension, bringing into being the King George V graving dock. The present docks establish Southampton as the leading British passenger port and the regular terminal of the Queen Elizabeth, Queen Mary, and Union-Castle liners, also of R.M.S.P. and C.P.R. liners (see Dock illus., pp. 2,755-57). During the Second Great War Southampton was the main base for U.S. forces. It is also an airline terminal and flying-boat base.

The district which is now Southampton was occupied in the Stone Age. The settlement of Clausentum established by the Romans was a link in their communications with the Continent. The Saxons first landed on the shores of Southampton Water, calling their settlement there Hamwi (it was excavated in 1950). During the visit of King Canute

the well-known story of his rebuking the courtiers originated. Development began after the Norman Conquest, when the town walls and the Bargate (still standing) were constructed. Other relics are the Red Lion inn referred to by Shakespeare in King Henry V, the Ancient Water House, the chapel of S. Julien, and Tudor House.

The modern civic centre provides excellent library, health, cultural, and educational services. The fine Guildhall accommodates over 2,000 people. A grammar school dates from 1554 and a university college from 1862. S. Michael's, the oldest church standing, is of Saxon and early Norman origin. S. Mary's, on which site the mother church of Southampton stood from the 11th century, and Holy Rood, dating from 1320, were damaged by bombs in the war. During 1940-44 the air raid warning was given 1,606 times, 631 people lost their lives, 5,000 properties were destroyed, 10,000 seriously damaged; the worst raids being on the nights of Nov. 30 and Dec. 1, 1940.

Here is one of England's largest oil storage centres; Schneider Trophy seaplanes and Spitfires were evolved; there are engineering works, iron and brass foundries, flour mills, and factories making chemicals, paints, plastics, gloves, and tobacco. There are commons, parks, a sports centre covering 268 acres, and the world's oldest bowling green (1299). Excursions to the New Forest are easy. See illus. facing p. 7677.

Southampton. Large island of Canada, in Hudson Bay. It lies S.W. of Fox Channel, and has the strait, Roe's Welcome, on the W.

Southampton, EARL OF. English title granted successively to the Fitzwilliam and the Wriothesley families. The first creation was in 1537, in favour of Sir William Fitzwilliam, keeper of the privy seal. On his death in 1542 the title became extinct, but was revived five years later for Thomas Wriothesley. He was the grandfather of Henry, 3rd earl (v.i.). The 4th earl Thomas (1607-67), was a staunch royalist, who held considerable property in London still associated with his name, e.g. Southampton Row. On his death the title became extinct.

Southampton, HENRY WRIOTHESLEY, 3RD EARL OF (1573-1624). English courtier and patron of letters. Born Oct. 6, 1573, he succeeded his father as earl in 1581, and studied at S. John's College,

Southampton arms

Cambridge, 1585-89. From 1590 he became known as a popular figure at court and a generous patron of the poets, notably Shakespeare, who dedicated to him *Venus and Adonis*, 1593, and *Lucrece*, 1594. It is held by some scholars that the Sonnets of Shakespeare are addressed to Southampton. He accompanied Essex to Cadiz and Ireland, and was imprisoned for complicity in Essex's rebellion. Released by James I, he died serving at Bergen-op-Zoom, Nov. 10, 1624.

3rd Earl of Southampton,
English courtier
After Mirevelt

He accompanied Essex to Cadiz and Ireland, and was imprisoned for complicity in Essex's rebellion. Released by James I, he died serving at Bergen-op-Zoom, Nov. 10, 1624.

SOUTHAMPTONSHIRE OR COUNTY OF SOUTHAMPTON. Official name of the English co. usually called Hampshire (*q.v.*).

Southampton Street. London thoroughfare. Opening N. from the Strand to Covent Garden, W.C., and laid out in 1704, it occupies part of the site of Bedford House, the residence of the earls and dukes of Bedford, 1552-1700.

Southampton Water. Opening of the English Channel. It extends from the Solent and Spithead for 10 m. inland. Its breadth is about 2 m. The Isle of Wight forms a natural breakwater, and the inlet is a safe harbour. The Test, Itchen, and Hamble flow into it.

South Australia. State of the commonwealth of Australia. Bordering all the other states except

South Australia
arms

Tasmania, it lies between Victoria and Western Australia along the S. coast. Its coast is ironbound and harbourless in the W., but indented by Spencer and St. Vincent Gulfs in the E. The W. of the state is occupied by the S. portion of the Central Australian plateau; here the Musgrave Ranges lie E.-W., and rise in Mt. Woodroffe to 5,200 ft., the highest point in the state. S. of Lake Gairdner, which occupies a depression in the plateau, are the Gawler Ranges. In the N.E. is the basin of internal drainage of Lake Eyre. Here are intermittent rivers, *e.g.* Barcoo and Frome, which flow only after torrential rains but which are frequently marked by water holes, useful on the stock routes. Only small streams reach the sea, except the lower Murray

Only in the Mt. Lofty ranges of the S. Australian Highlands, and among the volcanic mountains, including Mt. Gambier in the extreme S.E., does the annual rainfall exceed 30 ins., and except between Spencer Gulf and the Murray, it is less than 15 ins. per annum. The hills are forested with eucalyptus and acacia; the S. is sandy and limestone scrub; and the N. is part of the Central Australian Desert. Area of state, 380,070 sq. m.

Primary production is centred upon wheat and sheep growing, with some barley, oats, and hay. Although the main interest in sheep is wool, crossing of English breeds with the merino has produced excellent fat lambs. Fruits of all kinds flourish. Irrigation areas on the banks of the Murray from Renmark to Waikerie, developed for the settlement of ex-servicemen of the First Great War, became the centre of the dried and preserved fruit industry. Vineyards near Adelaide, Barossa, and in the Murray Irrigation area yield 75 p.c. of Australian wine. Uranium has been discovered, and copper is the mineral most profitably worked.

The railways are government-owned, and except for those on Eyre Peninsula which converge at Port Lincoln, the system centres on Adelaide. This is connected by rail to Melbourne and Perth. The projected line to Port Darwin extends to Alice Springs in Central Australia. Branch lines serve the main agricultural areas. For many years the line to Broken Hill, N.S.W., was the only rly. outlet from that important mining area to the sea, and its silver lead is carried to Port Pirie for smelting.

S. Australia sends 10 members to the federal senate and eight to the house of representatives; the state legislative council has 20 and house of assembly 39 members. Education is compulsory and free up to 14. The state prides itself on having been the first in Australia

to introduce town planning and public trustee acts and the extension of parl. franchise to women.

Pieter Nuyts discovered the S. coast, and reached Nuyts Archipelago in 1627. Lieutenant Grant reached Mt. Gambier from Botany Bay in 1800. Flinders in 1801 discovered Spencer Gulf and Kangaroo Island, and met the French exploring ship *Le Géographe* in Encounter Bay. Sturt sailed down the lower Murray in 1830. The first settlement was made by Thomas Whalley, on Kangaroo Island, in 1816. In 1836 the pioneer immi-

South Australia. Map of the progressive, wheat-producing, and fruit-growing state of the Australian Commonwealth

grant ship, closely followed by eight others, arrived, and Hindmarsh, the first governor, proclaimed the foundation of the colony. The pop. in 1838 numbered 3,680, mostly settled in or near Adelaide, the state capital; it is now 646,216. See Adelaide; Australia and map. Consult S. A., a Geographical Study, C. Fenner, 1931.

South Bend. City of Indiana, U.S.A. Situated on the St. Joseph river, in the co. of that name, and 85 m. E.S.E. by rly. from Chicago, it lies on the crest of the watershed separating the St. Lawrence and Mississippi river basins. It was an Indian settlement and a trading post; prosperity arose from the building of "prairie schooner" wagons for immigrants moving W., and it became a town in 1835. Aircraft, motor cars, sewing machines, and farm implements are manufactured. South Bend is the seat of the R.C. university of Notre Dame. Pop. 101,268

Southborough. Urban dist. of Kent, England. It is 2 m. N. of Tunbridge Wells and 33 m. S.E. of London, having a rly. station. With its chalybeate spring, it is mainly a residential area. Pop. est. 8,750. There is another Southborough in the same county, on Bromley common.

South Carolina. An Atlantic state of the U.S.A., and one of the 13 original states of the Union. Its area is 31,055 sq. m., rather more than that of Scotland. The surface rises from a low and level coast belt, largely under pinewood, to a height of more than 3,500 ft. in the W., where it is broken by mountain spurs of the Appalachian system. The coast is barred in parts by islands separated by narrow straits. The principal navigable rivers, all of which follow a S.E. course, are the Santee, formed by the confluence of the Congaree and Wateree, the Great Pedee (lower course), and the Savannah, which forms nearly the whole of the W. frontier.

S. Carolina is an outstanding recreational centre—the state with the longest open hunting season, and one in which the fishing season is never closed. It has 16 state parks with an area of 34,753 acres. The cotton crop excels all others in importance. Other products include tobacco, rice, maize, sweet potatoes, peanuts, peaches, and oats. Phosphate rock and granite are worked; oysters, whiting, and shad caught; cotton goods and lumber products, notably turpentine, manufactured. Until 1949 divorce was not allowed.

The Old Exchange Building in Charleston housed the first independent government established in U.S.A., which the S. Carolinians set up in 1774 during the revolutionary period. S. Carolina's secession from the Union, voted by her people in convention on Dec. 20, 1860, brought about the outbreak of the Civil War. The university of S. Carolina and 14 other institutions provide higher education. Two senators and six representatives are sent to congress. The capital is Columbia. Pop. 1,899,804, of whom 814,164 are negroes. *Consult* History of S.C., 4 vols., D. D. Wallace, 1934.

Southcott, JOANNA (1750–1814). English religious fanatic. Born at Gittisham, Devon, she was a domestic servant and shop assistant. Having joined the Methodists, about 1790 she began to write prophecies which attracted attention. Her followers became numerous, and in 1802 she settled

in London, where she began to “seal” the 144,000 elect. About this time a chapel was opened for her followers, and Joanna put forward the idea that she was about to become the mother of Shiloh, the second Christ (Rev. 12). Great preparations were made for the event, but on Oct. 29, 1814, she died of brain fever. Several collections of Joanna's prophecies are published, and a box said to hold others was the object of much interest until when opened it was found to contain junk. Her followers formed a religious sect, still existing in the 20th century.

South Dakota. North-central state of the U.S.A.; area, 77,047 sq. m., a million acres of which are

Joanna Southcott, religious fanatic

South Downs. A stretch of these English chalk uplands near Alfriston, Sussex

the Big Bad Lands, an expanse of ravines, clay bluffs, and no vegetation. The Grand, Moreau, Cheyenne, and Bad rivers in the W., and the James and Big Sioux in the E., are all tributary to the Missouri, which divides the state into two almost equal parts. The Black Hills, in the extreme W., rise to Harney Peak (7,242 ft.), the highest mt. E. of the Rockies. In these hills are found fossil deposits and archeological remains of a well organized prehistoric society. The “coyote state” is largely occupied with agriculture. Maize, wheat, oats, barley, rye, flax, potatoes, and some hardy fruits are grown, and the chief industry is processing these products. Among minerals gold and silver are mined most extensively; at Lead is the largest gold mine in the U.S.A. The state (admitted to the Union in 1889, and sending two senators and two representatives to congress) has a university, college of agriculture and mechanic arts, and school of mines. Pierre is the capital. The pop. is declining, for the 1940 census showed 642,961, and an est. of 1947 gave 564,000. Some 23,000 Indians have eight reservations.

South Downs. Range of English chalk uplands extending 60 m. E.S.E. from the W. borders of Sussex near Midhurst to the sea at Beachy Head. The downs once formed one range with the North Downs, but erosion has divided them by a lowland area, the Weald. They are breached by the rivers Arun, Adur, Ouse, and Cuckmere, and reach their highest point at Duncton Beacon (837 ft.). Rolling turf-covered hills provide fine scenery, and between them are unspoilt villages. Among well-known beauty spots are Devil's Dyke and Chancetonbury Ring. From Brighton the downs form a series of cliffs stretching E. to Beachy Head. In many places are earthworks and barrows built by the ancient Britons. Lewes, the co. town of E. Sussex, is in the midst of the downs.

The Southdown breed of sheep was brought to perfection by John Ellman (1753–1832), a farmer from Glynde.

South-East Asia Command.

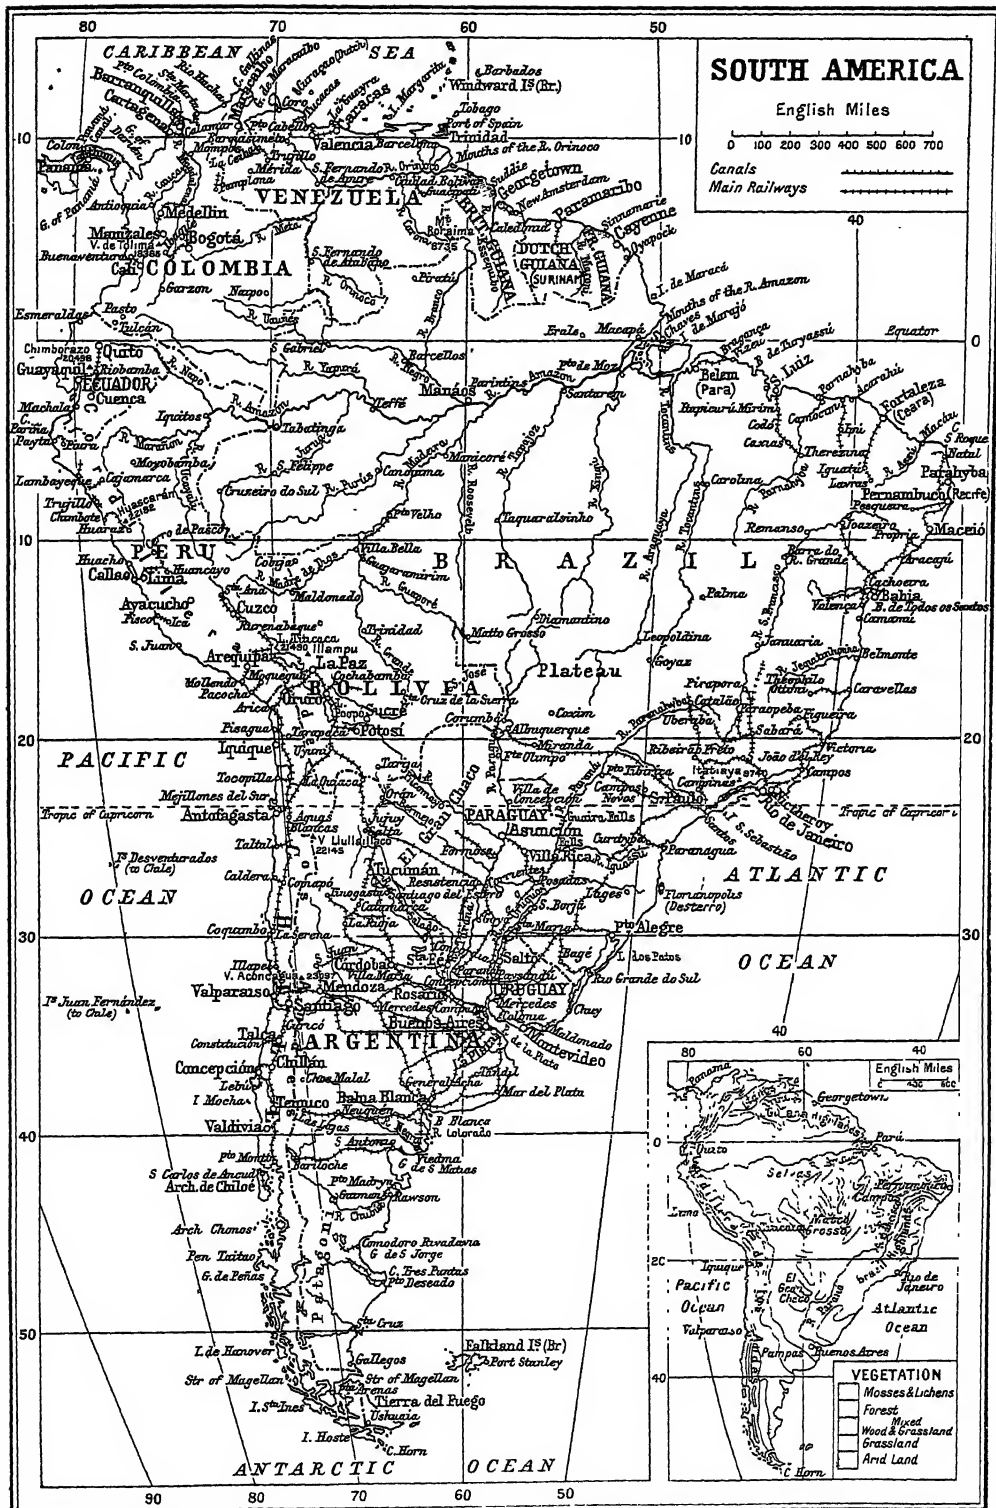

Authority in the Second Great War, set up on Aug. 24, 1943, after a meeting at Quebec between Winston Churchill, President Roosevelt, and T. V. Soong. With h.q. at New Delhi, and Lord Louis (later Earl) Mountbatten as the supreme Allied commander, S.E. Asia, it had as function coordination of all Allied land, sea, and air operations in Burma and Malaya, extended in Aug., 1945, to Indo-China and the Netherlands Indies. Gen. Stilwell (g.v.) was deputy supreme commander March–Oct., 1944. Mountbatten moved his h.q. to Kandy in Ceylon (which was under SEAC) April, 1944, and to Singapore Nov. 22, 1945. SEAC was dissolved Dec. 1, 1946.

Southend-on-Sea. County borough and seaside resort of Essex, England. It is on the N. bank of the Thames estuary, 36 m.

Southend arms

E. of London by rly., also connected by electric rly. with London's underground service (District line). Southend-on-Sea includes Westcliff, Thorpe

Fuller topographical details in the larger scale maps are given under the headings of the various countries

their departure in the Mayflower in 1620. 5 Air view of the Civic Centre (consisting of Guildhall, law courts, municipal offices, libraries and art galleries) as it appeared in 1939, before being partly damaged in German air raids

SOUTHAMPTON: HISTORIC SEAPORT ON THE ENGLISH SOUTH COAST. See p. 7674

Southend-on-Sea, Essex. An air view of this popular seaside resort on the Thames estuary

Bay, Shoeburyness, and Leigh-on-Sea. Features of Southend are a pier nearly $1\frac{1}{2}$ m. long, 7 m. of sea front and promenade, a swimming pool, wide sands, wooded cliffs, 16 pleasure grounds totalling 600 acres, amusement park, and sporting events which include a yachting week in July. During 1946 Southend had over 4 million visitors.

There are radio, electrical, and light engineering industries, plastics, textile, and furniture manufactures, brickmaking, boat building, and fishing. Until the beginning of the 19th century Southend was a village, but a bracing climate made it popular with Londoners. Buildings of interest in the neighbourhood are the 12th century priory at Prittlewell, and a ruined castle at Hadleigh. Southend was made a bor. in 1892, and a co. bor. in 1914. Up to 1950 it had one M.P., thereafter two. Pop. est. 147,410.

Southerly Burster. Strong, often violent, S. wind following a depression in S. and S.E. Australia, especially on the coast of N.S.W. It is accompanied by a sudden fall in temperature, sometimes 30–40° F. in 30 minutes, and frequently ends a Sydney heat wave. A well-defined roll of cumulus cloud with heavy rain, and sometimes thunder and lightning, are associated with the burster. These storms, most prevalent from Oct. to March, are similar to the line squalls of higher latitudes. See Squall.

Southern Alps. Mountain range of S. Island, New Zealand. It forms the backbone of the island for a length of more than 300 m. W. the mts. slope steeply through the forests to the Tasman Sea; E. lie the Canterbury Plains. Many glaciers feed the Waitaki, Rakaia, Waimakiriri, Hurunui, and other streams. The Tasman Glacier is one of the largest outside the polar

regions; others are Mueller, Hooker, Murchison, and Godley. Wakatipu, Wanaka, and Hawea are lakes of glacial origin. The range is snow-capped, and rises to Mt. Cook 12,349 ft. S.W. the range reaches the coast among the fjords, Milford Sound, etc. The Otira Gorge is the only easy passage through the range, which is one of

the finest mountainous tourist resorts in the S. hemisphere.

Southern Cross. Striking figure visible in the southern heavens, and formed by the four bright stars α , β , γ , and δ Crucis. The long arm of the cross (joining γ to α), if extended about five times its own length, passes close to the position of the S. pole of the sky, which is, however, not marked by any bright star. The Southern Cross is represented on the national flag of Australia.

Southerne, THOMAS (1659–1746). English dramatist. Of his comedies and tragedies, only the latter have any merit. The best are *The Fatal Marriage*, 1694, and *Oroonoko*, 1696, a vehement attack upon the slave trade. He died May 22, 1746. *A Life*, by J. W. Dodds, appeared in 1933.

Southern Railway. Former British railway company. Established in 1923, it was an amalgamation of the London and S.W.; London, Brighton and South Coast; S.E. and Chatham; and several smaller companies. The principal London termini were Waterloo, the largest station in Great Britain, handling 1,550 trains daily; Victoria; London Bridge; Cannon Street; and Charing Cross. Route mileage, 2,186, was less than one-eighth of the British main line total, but the Southern carried the densest traffic of any company, and over 25 p.c. of the passengers. It had 447 m. of electrified track by 1947, and carried the heaviest suburban traffic in the world. Covering the whole S. coast from Margate to Plymouth, the company sent electric trains as far as Portsmouth, and steam services into Cornwall and Devon. It had an extensive seaborne trade and Anglo-Continental traffic, owning 46 steamers. It ran the Golden Arrow express from London to

Paris and maintained two train ferries on cross-Channel routes. The company owned docks at Southampton, and ten large hotels in London and the provinces. In both Great Wars it carried the bulk of the troops and stores to the Continent. In 1948 it was absorbed into British Railways.

Southern Rhodesia. Self-governing British colony in S. central Africa, between 15° 30' and 22° 30' S. lat., and 25° and 33° E. long. Its area of 150,333 sq. m. is bounded on the N. by the river Zambezi, with Northern Rhodesia beyond; on the S. by the river Limpopo, with the prov. of Transvaal beyond; on the E. by Mozambique; and on the W. by the Bechuanaland Protectorate. It lies wholly in the tropics, on a plateau from 3,500 to 5,500 ft. in height, rising to a mountain range with peaks from 6,000 to 8,000 ft. high towards the E. The climate is generally suitable for European settlement, except in the hot and humid parts of the river valleys.

HISTORY. The area now called Southern Rhodesia is of immense antiquity, geological evidence pointing to the existence of human beings here at a much earlier period than in Europe or Asia. In the 15th and 16th centuries Portuguese missionaries and explorers reached the Rhodesian plateau, the first to take Christianity to the unusually savage and primitive tribes, and the second to seek the fabulous treasures supposed to be buried there. Neither the explorers nor the missionaries succeeded in their quest, and for another 200 years central Africa remained the "dark continent," a completely unknown and legendary land. It was left to the Scottish missionary Moffat, father-in-law of David Livingstone, to reawaken curiosity in the region. He established the first mission among the Matabele, a strong, warlike tribe, who waged constant warfare on their neighbours, particularly on the peaceful pastoral tribes of Mashonaland.

Great Britain, Germany, Italy, Portugal, Belgium, and the Transvaal republic all became competitors for a share in the unoccupied lands of central Africa. At first Great Britain was only mildly interested, and without the faith and pertinacity of Cecil Rhodes, Rhodesia might never have been included in the Commonwealth. On Oct. 29, 1889, he obtained from the British govt. a royal charter incorporating the British South Africa co. and conferring on it certain limited powers of administration

Southern Rhodesia. Map of the whole of Rhodesia, comprising Northern and Southern Rhodesia

over the territory between the Limpopo and the Zambezi. The area now Northern Rhodesia also came under the jurisdiction of the co.

Rhodes, who had obtained valuable concessions from Lobengula, chief of the Matabele, organized a pioneer column which marched from the border of Bechuanaland through trackless and difficult country, arriving at the site on which Salisbury now stands, Sept. 12, 1890. After several conflicts with the native inhabitants, notably the Matabele wars of 1893 and 1896, the pioneers triumphed, and since that time the relations between the different peoples of the area have been uninterruptedly harmonious.

For thirty years the average increase of the white pop. was about 1,030 per annum. The settlers built rlys., laid out towns, located the major mineral deposits, and began to develop both the mines and agriculture.

The British South Africa co., whose main commercial interests were transport, mining, and agriculture, paid its first dividend in 1923. It administered the country justly and with a view to its

development until its administrative charter was ended and Southern Rhodesia was formally annexed, Sept. 12, 1923; the settlers, given the choice of local autonomy or of accepting generous terms offered by Gen. Smuts to join the Union of South Africa, decided by referendum in favour of responsible government, which was established on Oct. 1.

ADMINISTRATION. Although a self-governing colony, Southern Rhodesia deals with the office of Commonwealth Relations in London. She has full control over her own internal affairs except in legislation affecting the native population.

The legislative assembly has 30 elected members and a speaker; there is no upper chamber, though provision exists for the creation of one if necessary. There is a cabinet, led by a prime minister, the other portfolios being native affairs; finance; internal affairs; mines and public works; commerce and industries; agriculture and lands; justice; works; and defence and air. The king is represented by the governor, who is also c.-in-c.

All British subjects, irrespective of sex or colour, are entitled to vote, provided they have resided six months in the country, occupy premises to the value of £150, have an income of not less than £100 a year, or own a registered mining location. In practice, this means that few natives have the vote. At the general election of 1946, the United party under Sir Godfrey Huggins, who first became prime minister in 1933, was returned with 14 seats, against 11 held by the Liberals and five by the two Labour groups.

In 1921 there were fewer than 34,000 European and about 899,000 native inhabitants. In 1948 the est. European pop. was 110,000, the native about 1½ millions. Coloured persons and Asiatics numbered 8,500. Land set aside for tribal settlements covers 21,127,040 acres, for native purchase 7,859,942 acres.

RESOURCES AND TRADE. The country was built up on gold mining, and gold remains important in its economy. There are also rich coal deposits, the field at Wankie being outstanding. Other natural assets include a large deposit of iron ore at Que Que, under govt. exploitation, and deposits of asbestos, chrome, and mica. Much land is suitable for agriculture and cattle rearing. In 1946 the total value of exports, 79 p.c. to British countries, was £16,586,000, chief items being tobacco leaf, gold bar, and chrome. Imports, 76.9 p.c. from British countries, were valued at £20,744,000, chief items being metals, manufactures, vehicles, yarns and textiles, food-stuffs, leather and rubber manufactures.

The govt.-controlled rlys. reach Northern Rhodesia at Victoria Falls, thence run to the Belgian border, and also link with Beira and the S. African rly. system. A line from Broken Hill to Tanganyika was begun 1949. There is a state air service.

In the two Great Wars Southern Rhodesia was responsible for her own defence and made substantial contributions in men and money to British forces. During the Second, she participated in the Commonwealth air training scheme; out of 19,000 European citizens of military age, more than 10,000 (including 1,400 women) joined the military forces of the Commonwealth; two Rhodesia squadrons served with the R.A.F.

The chief towns are Salisbury (pop. 69,049, including 21,293 Europeans), Bulawayo (51,698, in-

cluding 17,317 Europeans), Gwelo, Umtali, Que Que, Gatooma, and Wankie.

Walter C. Smith

Southernwood (*Artemisia abrotanum*). Shrubby perennial plant of the family Compositae. Growing native in Europe, it has insignificant flowers, but the plants are favoured because of their fragrant, feathery, hair-like foliage. In various parts of England it is known as old man, old woman, or lad's love. It may be raised from seed sown in March, or from cuttings, or from division of the roots taken later in the year. It will flourish in any open and unconfined position. See *Artemisia*.

Southernwood. Left, spray of flowers; right, sweet smelling leaves. Inset, left, flower-head; right, leaf

Southey, ROBERT (1774-1843). English poet and historian. He was born at Bristol, Aug. 12, 1774, the son of a linen draper, and went to Westminster and Balliol College, Oxford. Influenced by the French Revolution, Southey developed advanced ideas in politics and religion, and with Coleridge, whom he met in Oxford in 1794, cherished vain dreams of establishing a Pantisocracy or communal republic in the New World. Southey's advanced ideas were reflected in early literary efforts, *Wat Tyler*, a drama, and *Joan of Arc*, an historic epic. A trip through Spain and Portugal, 1795-96, inspired him with lifelong interest in those countries. *Thalaba the Destroyer*, a Mahomedan epic in irregular blank verse, was published in 1801.

By 1803 Southey had settled down to literature in earnest at

Robert Southey

Greta Hall, Keswick. He had married one of the three Misses Fricker, Coleridge marrying another. The Lake District was chosen as a place of residence on account of Southey's friendship with Coleridge; this intimacy was not to last, but at Keswick appeared a new friend in Wordsworth. A romantic Welsh epic, *Madoc*, was published in 1805; *The Curse of Kehama*, an epic of Hinduism, in 1810; and an historic epic, *Roderick, the Last of the Goths*, in 1814. Years of continuous overwork affected Southey's health, and when he died, March 21, 1843, he had been insane three years. Early republicanism having gradually changed to Toryism, he had been appointed poet laureate in 1813, and for two separate periods was in receipt of a government pension of £160, later £300.

Southey's output was prodigious, but his only enduring work is his *Life of Nelson*, 1813, written in lucid and direct prose. The same qualities are to be seen in his miscellany *The Doctor*, 1834-37. His prose works also include *Life of Wesley*, 1820; *History of the Peninsular War*, 1823-32. Much of his verse is dull and unimaginative,

but *After Blenheim* holds its place as a recitation; *Lodore* is a *tour de force* in rhyming; and there is nobility in the lines beginning, *My days among the dead are passed*.

Bibliography. *Poetical Works*, new ed. 1850; *Selected Poems*, 1895; *Life and Correspondence*, ed. C. C. Southey, 1849-50, Correspondence with Caroline Bowles, ed. E. Dowden, 1881; *Lives*, E. Dowden, new ed. 1895; J. Dennis, new ed. 1895; J. Simmons, 1845.

South Foreland, Cape of Kent, England. See *Foreland*, N. and S.

Southgate. Mun. bor. and bor. constituency of Middlesex, England, 1½ m. N.E. of New Southgate rly. station. It was the S. gate of Enfield Chase. Christ Church, 1863, is on the site of a chapel built in 1615 by Sir John Weld, of Arno's Grove, or Arnold's, later Minchenden. To the S. are Broomfield Park and Grovelands Park. Part of the dist. was in 1873 united with Colney Hatch (*q.v.*) to form New Southgate, and the Gothic church of S. Paul erected. Leigh Hunt was born at Southgate, and the lanes between Southgate and Colney Hatch were haunts of Charles Lamb. Pop. est. 74,000.

South Georgia. British island in the S. Atlantic Ocean. Situated 800 m. E. by S. of the Falkland Islands, of which it is a dependency, it is mountainous, from 6,000 to 8,000 ft. in elevation, with glaciers descending the gorges on the mountain slopes. It is uninhabited except for the whaling settlement, and is a sealing ground. Discovered in 1775 by Cook, it was visited in 1882-83 by a German scientific expedition to observe the transit of Venus. Here Sir Ernest Shackleton (*q.v.*) was buried in 1922. Ownership of Falkland Islands and their dependencies was disputed with the U.K. by Argentina from 1936 and by Chile from 1939. Area, est. 1,000 sq. m. Pop. est. 360. See *Antarctic Exploration*, p. 480.

South Georgia. Whaling station and mountains of Grytviken, from the sea, in the island at the gate of the Antarctic where Shackleton died and was buried

South Holland. Province of the Netherlands. See Holland. p. 4271.

South Island. Largest of the New Zealand islands. It lies between North and Stewart Islands, and has an area of 58,093 sq. m. The S. Alps form a mountainous backbone; E. of them lie the Canterbury Plains, the chief wheat-growing area in the dominion. Oats are grown in the S., and sheep are reared in the E.; dairy farming is profitable. Coal is mined in the N.W. South Island includes the districts of Marlborough, Nelson, Westland, Canterbury, and Otago, and the chief towns are Christchurch and Dunedin. Pop. est 600,000. See New Zealand.

South Lancashire Regiment. Unit of the British army. Formed in 1881 by an amalgamation of

South Lancashire Regiment badge

it adopted its present title.

Raised in 1717, the 40th Foot served in America until 1747. It then went to the W. Indies and fought at Martinique and St. Lucia. It was with Abercromby in Egypt in 1801 and then moved to the Peninsula, where twelve honours were won. It served in the American War of 1812, returning to Europe in time for Waterloo. The 82nd Foot was formed in 1793 and fought in the Peninsula. Thereafter both regiments served together in the Afghan War of 1842 and against the Mahrattas. Three honours were won in the Crimea and two in the Indian Mutiny. Both regiments took part in the Maori War of 1860-65. In the S. African War the Prince of Wales's Volunteers were with the Ladysmith relief force, and earned much distinction in the fighting for the Tugela Heights.

Twenty battalions were raised for service in the First Great War and, fighting on four fronts, earned the honours: Mons; Aisne, 1914, '18; Messines, 1914, '17, '18; Ypres, 1914, '15, '17; Somme, 1916, '18; Lys; Dorian, 1917, '18; Sari Bair; Bagdad; Baluchistan. In the Second Great War South Lancashire battalions served in India, Madagascar, N. Africa, and Burma. The regimental depot is at Warrington.

Southland. Former prov. of South Island, New Zealand. It has been merged in Otago (*q.v.*).

South Orkneys. Group of uninhabited British islands in the S. Atlantic Ocean. It is a dependency of the Falkland Islands, from which it is 790 m. to the S.E. Coronation Island is the largest. On Laurie Island the Argentine government maintains the magnetic and meteorological station established and occupied, 1902-04, by the Scottish Antarctic expedition. In 1948 the Argentine govt. made claims to sovereignty over the S. Orkneys similar to those put forward by Chile in the South Shetlands (*q.v.*). The group, discovered by George Powell in 1821 originally bore his name. Area, 800 sq. m.

South Pole. Lat. 90° S., one terminus of the earth's axis. It lies on an elevated plateau, covered by an ice sheet, and was first reached by Amundsen and Scott. It does not coincide with the S. magnetic pole, which is in position 71° 10' S., 150° 45' E. See Antarctic Exploration.

Southport. Co. and mun. borough and seaside resort of Lancashire, England. It stands at the mouth of the Ribble estuary, 18 m. N. of Liverpool by rly. The buildings, all modern, include the town hall, Cambridge hall, market halls, free

Southport arms

library, Atkinson art gallery and museum. There are a promenade, 3 m. long, a pier with an electric tramway, two theatres, and on the front a marine lake 1 m. long. The winter gardens contain a theatre, aquarium, and conservatory. Other favourite resorts are the botanic gardens, Princes Park, Hesketh Park, and Kew Gardens.

Southport developed wholly after 1800, and became a popular watering-place in the 19th century. In 1867 it was made a borough in 1905 a co. borough, and in 1918 a parl. borough returning one member. In 1912 it was extended to include the urban dist. of Birkdale, which lies to the S.

Market days, Wed. and Sat. Pop. est. 84,820.

Southsea. English holiday resort on the Hampshire coast. It is part of the city of Portsmouth (*q.v.*).

South Sea Arrowroot (*Tacca pinnatifida*) Perennial herb of the family Taccaceae. A native

South Sea Arrowroot. Spray of foliage and, right, tubers from which arrowroot is obtained

of the East Indies and Society Islands, it has tuberous rootstocks, like those of the potato, and rich in starch. The large leaves are cut into oval segments, and the greenish funnel-shaped flowers are clustered in a dense umbel, succeeded by large, pear-shaped, ribbed fruits. Strips of the leaves are plaited into hats, but the chief economic value of the plant is its yield of starch, obtained by rasping the tubers and macerating the material in water, the deposit being a fine kind of arrowroot (*q.v.*).

South Sea Bubble. Popular name given to a group of speculative financial schemes in England resulting in a crisis in 1720. In 1711 the Tories wished to have the financial support of a great commercial company to counter-balance the Whig Bank of England and East India Company; and the South Sea Company was started, having secured to it, under

Southport, Lancashire. Lord Street, the main thoroughfare, one of the most spaciouly planned streets in the British Isles

government guarantee, actual or anticipated commercial rights in consideration of which it took over £9,000,000 of the national debt, with the interest thereon secured upon the proceeds of certain specified taxes. Soon afterwards England and Europe generally were seized with an epidemic of speculation. In 1719 the company obtained further commercial concessions from the government, and proposed to take over the whole of the national debt, and to advance £7,500,000 to the government.

The scheme in itself was perhaps rash, but was at least sane. But unfortunately the speculative mania was at its height; the public was taught to believe that South Sea stock would yield enormous profits. Ministers used their position to share in the gamble. In spite of Walpole's warning the shares raced up. Everyone, rich or poor, scraped together every available penny to buy South Sea stock at any price. In the first six months of 1720 the price of £100 shares rose to £1,100; then a whole series of fraudulent companies suddenly collapsed.

The public soon took alarm, and in three months the shares had fallen to £150. Vast numbers were ruined, the government was driven from office as having been responsible, and Walpole was called in to remedy the disaster. About £2,000,000 was raised by the forfeiture of the property of directors and other persons who had made nefarious profits out of the transaction, the government resumed the national debt, and the company was reconstituted on a sober basis. *Consult The South Sea Bubble, L. Melville, 1921.*

South Shetlands. Group of uninhabited islands in the Antarctic Ocean. A British possession, the group forms a dependency of the Falkland Islands, covers 880 sq. m., and is 580 m. S.S.E. of Cape Horn. Clarence, Elephant, and Deception are the chief islands, which are mostly mountainous. Mt. Foster, on Smith Island, reaches 6,600 ft. The group is a great centre of the sealing industry. Discovered and explored, 1819-22, it was proclaimed a British possession in 1908. In 1947 a Chilean warship set up a permanent post on Greenwich Island in support of Chile's claim to sovereignty over the islands. Other bases were established in 1948. When Chile refused to submit the disputed

sovereignty to international arbitration the British govt. instructed the authorities in the islands to take all legal measures to safeguard the British title.

South Staffordshire Regiment. Unit of the British army.

It was formed in 1881 by an amalgamation of the 38th and 80th Foot. The 38th was raised in 1702 and first saw active service two years later with Rooke at the capture of

South Staffordshire Regiment badge

Gibraltar. For 60 years the regiment was in the W. Indies, gaining the honours Guadeloupe (1759) and Martinique (1762). It then moved to India, and remained there until the Napoleonic Wars, when it formed part of Abercromby's force in Egypt. Drafted to the Peninsula, it won ten battle honours under Wellington. In 1818 the 38th went to Cape Colony under Col. Graham; in the following year it defeated a large force of Kaffirs, and in recognition of the regiment's gallantry the site of the action is called Grahamstown.

Raised in 1793, the 80th Foot joined the 38th in the Peninsula and served until the end of the campaign. Both regiments fought in the Crimean War, Indian Mutiny, and Zulu War of 1878-79. After amalgamation in 1881 they served in the Egyptian campaign of 1882-85 and the S. African War. Eighteen battalions were raised for service in the First Great War, earning the honours: Mons; Marne, 1914; Aisne, 1914, '18; Ypres, 1914, '17; Loos; Somme, 1916, '18; Cambrai, 1917, '18; St. Quentin Canal; Vittorio Veneto; Suvla. In the Second Great War, battalions fought in France (1940), N. Africa, Italy, Burma, and N.W. Europe. The depot is at Lichfield.

South Victoria Land. Section of the Antarctic continent. It lies W. of the Ross Sea, in about 160° E. long., and stretches S. from Cape Adare. Near the sea and the Ross barrier ice it is mountainous. The N. coastal portion is deeply indented, and the S. portion cut off from the E. by a great fissure in the barrier ice. *See Antarctic Exploration.*

South Vietnam. Name given in 1949 to the territory of S.E. Asia formerly called Cochinchina (*q.v.*).

South Wales Borderers. Regiment of the British army.

Raised in 1689 as the 24th Foot, the regiment served under William III in Ireland and Flanders, and was in all Marlborough's major battles. It was at the defence of Minorca in 1756, and served throughout the Seven Years' War and the American War of Independence. The regiment gained its sphinx badge under Abercromby in Egypt in 1801, and took part in the capture of the Cape of Good Hope in 1806. In the Peninsular War it won nine battle honours and particular distinction at Burgos and Talavera. Further honours were gained in the Sikh War in 1848-49 and on the N.W. Frontier.

South Wales Borderers badge

Greatest day in the regiment's history was Jan. 22, 1879, when, although the 1st battalion was annihilated by the Zulus at Isandhlwana, a single company of the 2nd battalion defended Rorke's Drift (*q.v.*) against an enemy force 3,000 strong. Ten officers and others were awarded the V.C. in this campaign. To recognize the regiment's record in the Zulu War, Victoria granted it the wreath surrounding the badge. Similar wreaths in silver are carried on the staves of the regimental and king's colours. The regiment fought throughout the Burmese War of 1885-87 and the S. African War.

Eighteen battalions of the South Wales Borderers were raised for service in the First Great War and went to France, Macedonia, Gallipoli, and Mesopotamia, winning the battle honours: Mons; Marne, 1914; Gheluvelt; Somme, 1916, '18; Cambrai, 1917, '18; Dorian, 1917, '18; Landing at Helles; and Bagdad. In the Second Great War, battalions served in Norway, Iraq, N. Africa, India, Burma, and the liberation of Europe. The Monmouthshire Regiment (*q.v.*) forms Territorial battalions, and the regimental depot is at Brecon.

Southwark. A metropolitan borough of the co. of London. In the co. of Surrey, it is bounded N. by the Thames, S. by Camberwell, E. by Bermondsey, and W. by Lambeth. It is connected with the City of London by Blackfriars. Southwark, and London bridges, important road junctions being at St. George's Circus, and the Elephant and Castle. The name derives from the southward works or

fortifications of London, and in early times Southwark was the site of a Roman, and probably of a Danish, colony. Known as the Borough, since 1551 it has been a ward of the City of London — Bridge Ward Without. Here were Bankside (q.v.) and the 16th and 17th century pleasure ground known as Paris Garden. Its inns were famous, e.g. The Tabard of The Canterbury Tales, and the many coaching hosteleries of the 18th and early 19th centuries. Its prisons, its

Southwark arms

Southwark. The cathedral church of S. Saviour's, from the south. It dates from the early 12th century, and was restored in the late 19th

century," and its fair, which existed from 1462 to 1763, were notorious.

The seat of a bishopric from 1905, its most notable building is the cathedral church of S. Saviour. It was founded, according to tradition, as the church of a convent, by Marie Audery, daughter of a ferryman, and dedicated to the Virgin. Turned into a college for priests by Swithun, bishop of Winchester, in the 9th century, the buildings were reconstituted as an Augustinian monastery in 1106, when the church was built in the Norman style. Known as S. Mary Overy's or Overy's (*ofer*, bank; *rie*, river) until the Reformation, it was later known as S. Saviour's, and restored by Bishop Thorold in the 1880s, the renovated and partly rebuilt fabric being reopened in 1897. The pinnacled tower is 35 ft. sq. and 150 ft. high. Tombs include those of John Gower and Lancelot Andrewes. There are memorial windows to Shakespeare

and other dramatists associated with Southwark; a Shakespeare memorial chapel was opened in 1912. The chapel E. of the N. transept was restored in 1907 in memory of John Harvard. The Early English Lady chapel which replaced the chapel demolished in 1830 serves as the parish church.

Other notable buildings include S. George's church, rebuilt 1734-36, on the site of the church in which Gen. Monk was married to Anne Clarges; S. George's R.C. cathedral, 1840-48; the Metropolitan tabernacle; Guy's hospital. In Summer Street is one of the largest printing works of the Amalgamated Press (q.v.). The market, mainly for fruit and vegetables, dates from the time of Edward VI. Southwark Bridge, opened June 6, 1921, has five arches, and replaced a bridge built 1815-19. Southwark Park, 63 acres, opened in 1869, is in Rotherhithe (q.v.).

An industrial centre, Southwark was formerly one of the most populous, and perhaps the poorest area in the country. It suffered heavily as a result of German air raids during the Second Great War, particularly in the neighbourhood of the Elephant and Castle. In 1950 its M.P.s were reduced from three to one. Pop. est. 96,000. See Bankside; Globe Theatre; Harvard, John; London; consult also Old Southwark and Its People, W. Rendle, 1878; Sketches of Southwark, R. W. Bowers, 1902.

Southwell. A city of Notts, England. It is 14 m. N.E. of Nottingham, with a rly. station, and has some manufacturing industries. The cathedral, or minster, dates mainly from the 12th century. It is a beautiful cruciform building, with Norman nave and towers and Early English choir. The chapter house is especially notable. The grammar school dates from the 16th century. Southwell was in 1884 made the

Southwell, Nottinghamshire. West front of the 12th cent. minster, made a cathedral in 1884

seat of a bishop. The diocese covered the counties of Nottingham and Derby until the diocese of Derby took away the latter. Pop. 2,991.

Southwell, ROBERT (1561-95). English Jesuit and poet. Born at Horsham St. Faith, Norwich, and educated at Douai and Paris, he was in 1577 received into the Society of Jesus at Rome, where he became prefect of the English college. Ordained priest

Robert Southwell, English Jesuit
After H. C. Vroom

in 1584, he returned to England in 1587 to minister to his co-religionists in defiance of the Act excluding English-born R.C. priests from the kingdom, and became chaplain to the countess of Arundel. Betrayed in 1592, he was cast into the Tower, racked 13 times, and hanged at Tyburn, Feb. 21, 1595. Of his poems, the longest is Saint Peter's Complaint, and the best known The Burning Babe, which Jonson praised to Drummond. Consult Robert Southwell the Writer, P. Janelle, 1935.

South-West Africa. Territory in Africa, formerly German, mandated in 1920 by the League of Nations to the Union of S. Africa. By the S.W. Africa Affairs (Amendment) Act, 1949, the Union assumed full powers of government. See N.V.

The territory has an area of 322,460 sq. m. It lies between Angola on the N. and the province of the Cape of Good Hope on the S., the Orange river being the boundary there. On the E. are the Bechuanaland Protectorate and British Bechuanaland, while W. lies the Atlantic, with a coastline of about 800 m. Walvis Bay, a small enclave on the coast, belongs to the Cape, as it did when this region was German. Windhoek, 180 m. inland from Swakopmund, is the chief town; others are Swakopmund, Seeheim, Karibib, Keetmanshoop, and Tsumeb. The chief harbours are at Swakopmund and Lüderitz Bay, but neither is as good as Walvis Bay.

The pop. is est. at 307,589. Many are Hottentots and Bushmen, while others belong to the Bantu group. The N. central part of the country is sometimes called Damara-land or Hereroland, N. of it is Ovambo, and S. is Great Namaqualand. In 1925 a constitution,

providing for an executive council, an advisory council, and a legislative assembly, was granted. Since 1947 S.W. Africa has sent representatives to the Union parliament. (See N.V.)

Most of the territory is barren and waterless, especially in the N. and E. Along the coast is a level, sandy strip 60 m. wide, which gives way to a mountain range with peaks nearly 9,000 ft. high. Farther inland is the Waterberg range, while the Karas Mts. are in the S.E. In the E. is the Kalahari desert.

The climate is warm, and there is a dry season from May to Sept., and a wet one for the rest of the year. Rainfall is scanty on the coast. The mean temp. in summer is 70° F., and in winter 50° F. At Swakopmund fog is recorded 150 days a year. Vegetation varies from the luxuriant palms and other trees of the tropics found in the valleys, to the coarse grasses growing on the desert sand. Among animals are antelopes, monkeys, jackals, hyenas, snakes, and crocodiles.

The chief native industry is keeping cattle, sheep, and goats. Some of the soil is cultivated, the crops including small quantities of wheat, maize, tobacco, and cotton. Fruit, including grapes, and vegetables are grown. The main exports are minerals, mainly tin and vanadium, dairy produce, pelts, guano, and ostrich feathers. The country has a rly. system based on the two ports, Walvis Bay and Lüderitz. From these lines run respectively to Windhoek in the N. and Keetmanshoop in the S., these two places being also linked together. The rlys. are connected with the system of the Cape. There are also well developed motor roads, linking the country with Angola.

The Portuguese were the first Europeans to land in S.W. Africa, but they did not take possession of it. Soon after 1800 some missionaries entered the land. In 1867 Great Britain annexed the islands off the coast, and in 1878 Walvis Bay. In 1883 a German merchant named Lüderitz made the port now named after him into a trading station. Acting unofficially, he had by treaty with a native chief obtained about 200 sq. m. of land there, and in 1884 the district was declared a German protectorate.

FIRST GREAT WAR. On the outbreak of war, Gen. Botha, Gen. Smuts, and the South African government affirmed their loyalty

to the British Empire, and it was indicated to them that the most useful thing they could do at first was to conquer German South-West Africa.

For the first two months of war all went well. Lüderitz Bay (Angra Pequena) was occupied, and a German raiding force was driven back over the Orange river, but until the end of the year progress was hampered by the rebellion in S. Africa (see South Africa).

Early in Dec., 1914, the garrison of Lüderitz Bay was reinforced, and preparations to repair the rly. there were begun. On Christmas Day Col. Skinner began the landing of a division at Walvis Bay. The Germans retired unresisting, and on Jan. 14, 1915, Skinner made a long night march with the Imperial Light Horse and took Swakopmund. Water supply was the great difficulty.

The lines of advance to the capital, Windhoek, had to be determined by rlys., for until the high veld was reached all water supply had to come up from Cape Town. The Germans had constructed rlys. of metre gauge from Orange river, the southern boundary, via Warmbad to Keetmanshoop, where a branch from Lüderitz Bay joined up, northwards to Windhoek, and was then continued in the direction of Swakopmund as far as Karibib; from here there was a light rly. to the coast at Swakopmund. Skinner's first work was to connect this with the base at Walvis Bay, and convert it to metre gauge.

The invasion was arranged in four columns to converge on Windhoek. In all about 50,000 men were employed. The only British regulars were a few officers and a small body of marine artillery lent by the Admiralty to raise and train heavy artillery. The field artillery were mainly British volunteers from the Transvaal and Natal. The mounted troops, of which each column was largely composed, included

the Imperial Light Horse from the Rand. The infantry brigades were mostly volunteer corps, and the young soldiers of the defence force were mainly drawn from the large towns.

Botha, in charge of the northern column, went up to Swakopmund in the early spring of 1915, and from that time events moved rapidly. He pushed rapidly up the bed of the Swakop river, without waiting for the rly. The Swakop was in flood during Feb., and Skinner's first rail from Walvis to Swakopmund running across the bed was swept away by the torrent. It was nevertheless a fortunate happening, as the unexpected water supply rendered possible Botha's sweep up to Karibib and Windhoek, which he entered in May. Meanwhile, the other columns had been making strenuous efforts to cross their respective tracts of desert. When they united, Smuts for a short period took command of the three and rapidly pushed them northward, but Botha's victorious entry into Windhoek soon left him free to carry on his more important work.

The German leader Francke, who had under him about 10,000 men, had evacuated Windhoek a week before Botha's entrance, and had retired along the Otavi rly. to the N. He now asked for an armistice, but on terms impossible to grant, and Botha, after a pause at Karibib to reorganize, followed

South-West Africa. Map of the territory administered by the Union of South Africa

him N., and after more stupendous treks compelled his unconditional surrender on July 9. See Damara-land; Herero; Lüderitz Bay.

Southwick. Name of several places in England, meaning south settlement. Southwick-on-Wear, Durham co., is virtually an industrial suburb of Sunderland, with shipbuilding yards. Another Southwick is a village on the Sussex coast, 4 m. W. of Brighton. with a rly. station.

Southwold. Mun. bor., seaport, and market town of Suffolk, England. It stands on the E. coast,

Southwold, Suffolk. Parish church of S. Edmund from the south-west

at the mouth of the Blythe, 41 m. N.E. of Ipswich. It is a watering-place and has herring, cod, and sole fisheries. The chief building is the church of S. Edmund, a fine Perpendicular building of the 15th century. There are a harbour and a pier, also an extensive common. An Anglo-Saxon settlement, Southwold became a busy seaport in the 13th century or earlier, having a market and fair. Before the Second Great War the duke of York's camp for boys, founded by King George VI when duke of York, and regularly visited by him, was held here in many summers. In the bay, also called Sole Bay (*q.v.*), English and Dutch ships fought an indecisive action, May 28, 1672. In the First Great War Southwold was bombarded by German vessels, Jan. 27, 1917. Market day, Thurs. Pop. 2,753.

Southwood, JULIUS SALTER ELIAS, VISCOUNT (1873-1946). British newspaper owner. Born in

Lord Southwood, British newspaper owner

Birmingham, June 5, 1873, he had little formal education; he delivered newspapers in London before entering as junior clerk the office of Odhams Bros., printers,

where he worked his way up to chairman and managing director. Odhams Press Ltd. became under Elias one of the biggest British houses issuing periodicals and newspapers. He acquired John Bull, The People, and in 1929 joint ownership (with the T.U.C.) of the Daily Herald. Active in many benevolent causes, he was chairman of the Red Cross penny-a-week fund which raised £17,500,000 during the Second Great War, and of the Great Ormond Street hospital for children. He gave the John Burns collection of books on London to the L.C.C. in 1943. In 1937 he was created a baron, and a viscounty was conferred just before his death, April 10, 1946.

Souza-Botelho, ADELE MARIE EMILIE FILLEUL, MARQUISE DE (1761-1836). French novelist. She was born in Paris, May 14, 1761, and in 1779 married the comte de Flahaut. During the Revolution she fled to England and Germany, her husband being a victim of the guillotine. While in exile she published the first of her novels, the delightful domestic story, *Adèle de Sénange*, 1794. In 1804 she returned to Paris and married the Portuguese minister, the marquis de Souza-Botelho. She died April 16, 1836. Her works were edited by C. A. Sainte-Beuve, 1840.

Sovereign. Coin which, although no longer minted for circulation, remains the standard of the

Sovereign. Reverse and obverse of the British gold coin. Actual diameter $\frac{1}{2}$ in.

British coinage. It consisted of 113,0016 grains of gold and 10,2728 grains of alloy, chiefly copper; and replaced the guinea as the principal coin in 1817. A sovereign weighing 240 grains had been introduced by Henry VII, one of the first English coins on which a serious attempt at portraiture was made. Until called in early in the First Great War, when Treasury notes were issued to replace them, gold coins included sovereigns and half-sovereigns. To celebrate the coronation of King George VI, tokens for £5, £2, £1, and 10s. were issued as collectors' pieces. Banknotes have now entirely replaced gold coins.

Sovereignty. Term used in political science to denote the possession of supreme power, "that absolute despotic power which must in all governments reside somewhere" (Blackstone). The nature of sovereignty has been much discussed throughout the centuries; the question whether it is desirable and practicable to surrender part of the sovereignty of nations to an international body is of current importance.

Hobbes and Austin both recognized that sovereignty might reside in one man or in a number. In any state there must be some final power to decide and to exact obedience; but this becomes a reality only when it cannot be interfered with from outside the state. In Great Britain legal sovereignty rests with the high court of parliament (*i.e.* the king, house of lords, and house of commons), which has "the right to make or unmake any law whatever." Dominion parliaments since the passing of the Statute of Westminster, 1931, have possessed full sovereignty. In the U.S.A. sovereignty is divided by the separation of powers among the president as chief of the executive, congress as the legislature, the supreme court as interpreter of the constitution, and the states through their power to amend it.

Dicey carefully distinguishes legal from political sovereignty; the latter, he holds, rests with the electorate. In any democratic country the position is similar, a test of democracy being the power of changing its government. Even in an autocracy there are limits to sovereignty, *e.g.* the impact of foreign affairs, or the certainty of resistance or disobedience by minorities.

The relationship between the sovereigns or governments of states, the extent to which one of them has the right to limit what the other may do in its own territory, is the province of international law. By every treaty a state surrenders something of its sovereignty. In addition, during the centuries a body of international law, or law of nations, has been evolved, which limits what a sovereign may do within its own territory. The League of Nations, the permanent court of international justice, and U.N.O. presuppose this law of nations. An urgent need today is to devise means by which states can delegate their sovereignty to international agencies in assurance that security and international co-

operation will thus be advanced. The opposition to the proposal for an international atomic energy commission was an emphatic reminder of the importance still attached to sovereignty. See Divine Right; Federalism; King; State. Consult Law of the Constitution, A. V. Dicey, 1885; Problem of Sovereignty, H. J. Laski, 1917.

Soviet (Russian *soviet*, council). Term, meaning originally simply council, which came all over the world to mean the particular kind of councils that until 1936 administered, at all stages, the affairs of the U.S.S.R. The first soviet in this political sense; a committee elected by strikers, met at Ivanovo Voznesensk in 1906, during a general strike. Similar committees were soon set up in Moscow, St. Petersburg, Samara (Kuibishev), Rostov, and other cities. They forced the administration to remedy some of the workers' grievances. Independent of political parties, they were, however, usually convened by members of the Marxist Socialist (Bolshevik) party. When the tsarist regime collapsed in 1917, soviets of the same kind again sprang into being in the factories. At first the Mensheviks and left-wing Revolutionary Socialists had a majority in them; but within a few months the Bolsheviks had secured control of all the principal soviets. The forming of soviets spread to the army and to the villages, and Lenin seized upon them as a suitable means of administration free from all bourgeois associations. Members of local soviets were at first elected by manual and brain workers of 18 and over; district soviets by the local ones, regional soviets by those of the districts, and the All-Russian congress of soviets by those of the regions. This system of indirect election was abolished by the Stalin constitution of 1936, which introduced direct election to the principal administrative body, called the supreme council of the U.S.S.R. Consult Soviet Communism, S. and B. Webb, 1941.

Soviet Central Asia. Area within the U.S.S.R., extending from the Caspian Sea in the W. to the Tien Shan Mts. and the Sinkiang prov. of China in the E., and touching Afghanistan on the S. It embraces five constituent republics of the Soviet Union; Kazakh, to the N., has an area of 1,072,797 sq. m., and is larger than the others combined, which are Kirghiz, Tadzhik, Turkmen, and Uzbek. The area was once generally known as Russian Turkistan.

Each of the republics has its individual entry in this work.

Sovietsky. Name given by the U.S.S.R. to Tilsit, a town formerly in East Prussia, upon its annexation in 1945. See Tilsit.

Sow. Word of A.S. origin for the female of the pig, and by analogy used for the female of the guinea-pig and hedgehog.

Sowerby Bridge. A dist. of Yorkshire (W. R.), in the land. It comprises the former urban dists. of Sowerby Bridge, Sowerby, Luddendenfoot, and Midgley, and the parish of Norland; and is in the co. constituency of Sowerby. On the Calder and Ryburn, 3 m. W. of Halifax, it is a rly. junction. It manufactures woollen, worsted, and cotton goods, and carpets, and has engineering works. Pop. est. 19,515.

Sowing. Farm and garden process for ensuring a new crop by depositing seeds in the soil. The ideal to be aimed at is to get the maximum number of mature plants upon a certain area that will have sufficient space for root development and a proper share of light and air; but the methods practised have to be varied according to the character of the desired crop, size of seed, etc. The surface soil must be brought to a suitable condition of lightness by plough or spade and atmospheric influence.

For field culture the ancient method of sowing broadcast is still followed in places, but mechanical drills are usually preferred. The sower walked the ridges with his "seed-lop" full of seed slung from his shoulder, and taking a handful of the seed cast it evenly in the furrows by a semi-circular sweep of the arm. Although great accuracy is attained by practice in this method, it is necessarily wasteful; and Jethro Tull, the father of modern British husbandry, in the first half of the 18th century invented a drill plough which sowed the seed-corn in parallel lines. From this original corn-drill many highly practical machines have been developed; and by some forms a suitable fertiliser is distributed with the seeds.

In vegetable and flower gardens sowing has to be done by hand, and the chief sowing time is the spring for most hardy annuals and perennials; for certain species, however, the autumn is more favourable. For biennials and tender annuals it is better to sow in May. The ground, well dug in autumn and left rough for the full influence

of frost, is in spring raked to a fine tilth, all stones being removed. Then, by means of a taut line and the hoe, shallow and parallel trenches are traced, their depth and width proportioned to the sizes of the seeds.

The seeds are distributed thinly and evenly along these drills and covered lightly with fine earth. With large hard-coated seeds like those of the pea and bean family, it is advisable to soak them in water for about 12 hours before sowing; and seeds of cannas have the integument so hard that one small spot should be thinned by rubbing on a file, to make it possible for moisture to enter. After sowing, the surface should be sprinkled with water. See Agriculture; Seed.

Sow-Thistle (*Sonchus*). Genus of tender herbs with milky juice, of the family Compositae. Natives

Sow-Thistle. Yellow composite flower-heads and glaucous leaves of the corn sow-thistle

of the temperate regions, they have brittle, hollow stems, and alternate leaves with toothed lobes. The flower-heads are yellow, all the florets strap-shaped. The fruits are flat and ribbed, with numerous silky hairs attached. There are three British species. The corn sow-thistle (*S. arvensis*) is a fine perennial with stout creeping rootstock, stems 2 or 3 ft. high, ending in yellow flower-heads a couple of inches across. The common sow-thistle (*S. oleraceus*) is an annual, and smaller.

Soxhlet Apparatus. Chemical apparatus consisting of a glass flask and condenser used for the automatic extraction of fats or other alcohol-soluble or ether-soluble materials.

Soy (Jap. *shoyu*). Piquant sauce, extensively used in Japan. It is made of soya beans boiled with coarse wheat or barley meal, fermented, and mixed with salt.

Soya Bean OR SOY BEAN (*Glycine soja*). Annual herb of the family Leguminosae, indigenous to tropical Asia. It is one of the

most important oil seed crops of the world, annual production of China and Manchuria being about 12,000,000 tons. In the Far East it has been an important crop from antiquity and is referred to in a Chinese *materia medica* written over 4,500 years ago. Since 1908 it has become a valuable raw material to western civilization, and in the U.S.A. production increased from 800 tons in 1922 to 600,000 in 1942.

The seeds contain about 18 p.c. oil, 40 p.c. albuminoids, and 22 p.c. carbohydrate. The oil, of the semi-drying type, and edible, is used in margarine and in soap. With suitable dryers it can be used in paint and varnishes, replacing about 25 p.c. of the linseed oil, and in the manufacture of alkyl resins for paint, varnish and printing ink. High albuminoid content makes the cake left after expressing the oil an excellent food for milking cows and other cattle. If the oil is completely removed the residue has uses in plastics and adhesives. About 70 p.c. of the plywood made in the U.S.A. is bonded with glues made from soya bean. The moulding industry makes use of soya meal.

In phenol formaldehyde moulding powders, soya can replace about a quarter of the wood filler. The protein reacts with the formaldehyde, thus becoming an active agent and not merely a filler. With formaldehyde alone the soya protein hardens; this property has been utilised in the production of artificial fibres.

The protein is dissolved in alkali and then spun in an acid bath. The thread is stretched and hardened by treatment with formaldehyde. Tensile strength is only 80 p.c. that of wool, but the substance is more resistant to moth and less readily wetted than wool.

The casein from soya bean has the advantage over milk casein in that the supply is not seasonal, is virtually unlimited, and can be used for industrial purposes without encroaching on the world food supply.

Soyer, ALEXIS BENOIT (1809-58). French cook. Born at Meaux, he became famous as a chef in Paris, but fled to England on the outbreak of the Revolution of

Alexis Soyer,
French cook
After Emma Soyer

point him to establish food kitchens in Dublin to relieve the distress. In 1855 he went to the Crimea and, with Florence Nightingale, reorganized the system of the food supply. He died in London, Aug. 8, 1858. He wrote *The Shilling Cookery Book*, 1854.

Spa. Name given to a health resort at which natural waters or baths can be taken for therapeutic purposes. It is derived from Spa (*v.i.*) in Belgium, one of the oldest watering-places. Many forms of natural water exist, suitable for the treatment of various complaints, but the particular character of the water is not the sole factor which gives a spa its therapeutic efficiency.

Hygienic living for a period is often at least as beneficial as the actual taking of the waters. The question of climate has also to be considered, some spas being mild and relatively humid, while others are dry and bracing. A person taking a course of medical baths or waters should place himself under medical advice, and follow a definite system of living, in which due consideration is given to diet, exercises, hours of sleep, and other adjuncts of treatment.

The following are the principal British spas: Bath has been celebrated for the virtue of its waters since Roman times. The thermal waters here range in temperature from 104° to 120° F., and contain calcium and sodium sulphate and magnesium chloride. They are recommended for chronic diseases of the digestive organs, subacute neuritis, sciatica, rheumatoid arthritis, mucous colitis, and skin affections such as eczema and psoriasis. Bath is low-lying, and is most suitable as a health resort from autumn to spring. Bridge of Allan contains a saline spring useful in catarrhal dyspepsia and disorders of the liver. The climate is mild.

1830. He was head cook at the Reform Club, 1837-50, and the practical interest he showed in the Irish famine of 1847 caused the government to ap-

Buxton stands at an elevation of about 1,000 ft., and its climate is dry and bracing, but cold in winter. The waters have a temperature of 82° F., and are recommended for the treatment of rheumatism, gout, etc. Cheltenham has waters rich in sodium chloride and sulphate, useful in liver and stomach troubles. Droitwich possesses saturated brine baths, which have been found helpful in lumbago, sciatica, and rheumatic affections, neuritis, neuralgia, anaemia, and chronic eczema. Brine baths are also to be found at Nantwich and Northwich.

Harrogate is dry and bracing. The springs consist mainly of two groups: sulphur waters useful in chronic gout, sluggishness of the liver, gastric and intestinal catarrh, and skin diseases, such as gouty eczema and psoriasis; and iron waters useful in anaemia, general debility, and convalescence after severe illness. Leamington is dry and warm. The principal constituent of the waters is sodium chloride. They are mildly aperient, and are useful for dyspepsia and disorders of the liver. Llandrindod has salt waters, some of which also contain sulphuretted hydrogen. These waters have a mild, aperient action, and also stimulate the kidneys. Matlock Bath has waters of a temperature of 70° F. At Strathpeffer are saline springs containing sulphuretted hydrogen. Woodhall Spa, Lincs., has bromo-iodine waters.

In France the chief natural waters are found at Plombières, St. Amand, Mont Doré, Aix-les-Bains, Bourbon l'Archambault, Châtel-Guyon, Vichy, Vals, Royat, Salins-Moutiers, Contrexéville, Martigny-les-Bains, Vittel, and Vernet-les-Bains. In Switzerland there are natural waters at Ragatz-Pfäfers, St. Moritz, Baden, and Weissenburg; in Italy at Salsomaggiore, Abano, and Montecatini; in Germany at Baden-Baden, Wiesbaden, Nauheim, etc., and in Czechoslovakia at Carlsbad and Marienbad. See Baths; Mineral Waters.

Spa. Town of Belgium, in the prov. of Liège. It lies in hilly, wooded, and picturesque country, on the Wayai, 21 m. by rly. S.E. of Liège. At this famous watering-place, the chief of its scattered springs is the Pouhon (Walloon, spring), others being the Géronstère and Prince de Condé springs; the waters (iron and carbon dioxide) are bottled for export. There are attractive promenades, kursal, racecourse, golf course, etc. The picturesque Lac de Warfaz lies 1½ m. N.E. of the town.

Soya Bean. Leaves and buds; inset, pods containing beans

Spa, Belgium. General view of this famous Belgian watering-place

Spa has flourished as a resort since the 16th century, was the most noted in Europe in the 18th century, and was visited by Peter the Great in 1717. Occupied by the Germans in the First Great War from Aug. 4, 1914, it became their G.H.Q. in March, 1918, and the emperor William II lived at the Château du Neubois, near Spa. Here took place the meetings which immediately preceded his flight into Holland, Nov. 8, 1918. Spa was the meeting place of the armistice commission, and in 1920 of the council at which decisions concerning reparations were made. Again occupied by the Germans soon after their invasion in 1940, Spa was liberated by the U.S. 1st army on Sept. 12, 1944.

Spaak, PAUL HENRI (b. 1899). Belgian statesman. Born in Brussels, Jan. 25, 1899, he studied

Paul Spaak,
Belgian statesman

law at its university and became a barrister. Elected Socialist deputy for Brussels in 1932, he became minister of posts and transport in the Van Zeeland government, 1935, and was minister of foreign affairs and trade, 1936-38. Holding that Belgium should remain neutral in the event of war, he conducted negotiations releasing his country from commitments under the Locarno pact and Anglo-French-Belgian agreements. Premier from May, 1938, to Feb., 1939, Spaak again became foreign minister at the outbreak of the Second Great War, and remained so when the Belgian government was exiled in London. He returned to Belgium upon its liberation in 1944, becoming deputy prime

minister under A. van Acker, then his successor for a few weeks, and leading the Belgian delegation to San Francisco. In 1946 he was elected president of the first U.N. general assembly and chairman of the peace conference in London. Premier a third time, 1947-49, he was chosen chairman of the Organisation for European Economic Cooperation (O.E.E.C.), 1948, and president of the assembly of the Council of Europe, 1949.

Spaatz, CARL ANDREW (b. 1891). U.S. army air officer. Born June 23, 1891, he led an air pursuit squadron in France, 1917-18. In the Second Great War he was chief of staff to Gen. Arnold, 1941, and American air commander in Europe, 1942. Spaatz was Allied air commander in the Mediterranean, 1943, commander of U.S. strategic air forces in N.W. Europe, 1944, and was witness to the German surrender at Reims, May 7, 1945, and U.S. representative at the ratification in Berlin, May 8. He was head of the U.S. strategic air force in the Pacific when atomic bombs were dropped on Japan, becoming chief of all U.S. air forces, 1946-48.

Space. One of the fundamental or ultimate concepts. Philosophically it has been explained as continuous extension, or extension as distinct from material substance—phrases which involve the conception itself. Leibniz defined space as the order of possible co-existences. Newton stated that absolute space, in its own nature, without relation to anything external, remains always similar and immovable. Kant conceived space as an *a priori* form of perception. Bergson thought of it as an order, but not the original order of reality, which is time. The theory of relativity (*q.v.*) invalidates the distinction between a three-dimen-

sional space and an independent time, replacing them by a four-dimensional space-time continuum. Many kinds of space are intelligible only to the mathematician and expressible only in mathematical symbols: space of *n*-dimensions, non-Euclidean space, curved space, finite space. *Consult* Time and Free Will, H. Bergson, 1910; *Geometry of Time and Space*, A. A. Robb, 1936.

Spade. One of the black suits in a pack of playing cards; or any card belonging to that suit. Spades began as swords or pikes (Fr. *pique*), and in the Middle Ages doubtless stood for the military class among the four orders of the community. Since then they have acquired a bad reputation. Napoleon I regarded the eight of spades as a card indicating disaster, and the ace of spades has become a symbol of death. This card is usually ornamented in English packs and may bear the maker's name. At bridge, spades were originally the lowest ranking suit, but at auction and contract bridge they are the highest.

Spade Guinea. Popular name for the guinea coined in the reign of George III. It was so called because it bore a spade-shaped shield on its reverse side. *See* Guinea.

Spadix (Gr., a fruiting palm-branch). Form of inflorescence in which many small flowers are clustered round a fleshy spike, often enclosed by a spathe. Examples are afforded by the wake robin (*Arum maculatum*), which has a spathe, and the sweet flag (*Acorus calamus*), which has the spadix naked. It is the form of inflorescence in flamingo-flower (*Anthurium*), palms, calla (*q.v.*), and *Richardia*. *See* Inflorescence; Konjak; Wake-Robin.

Spaghetti (Ital., little ropes). Farinaceous food. It is made of the same paste as macaroni, pressed out into a solid cord-like form thicker than vermicelli. It is cooked with cheese, meat, tomatoes, etc., and is used for puddings and savouries. *See* Macaroni.

Spahi (Persian *sipahi*, soldier, mounted warrior). Name given to men of the Algerian and Tunisian cavalry regiments in the French army. Originating in the Turkish army, the spahis were horsemen furnished by the sultan's feudal lords, and enjoyed a great reputation for valour and loyalty. On their occupation of Algiers and Tunis the French incorporated the Turkish native regiments in their own army, supplying French officers. The word is identical with sepy (*q.v.*). *See* Africa.

SPAIN: ITS HISTORY AND ITS PEOPLES

* ALFONSO LOPEZ, Spanish Writer and Translator

Numerous articles throughout this Encyclopedia describe the cities, towns, and rivers, e.g. Madrid, Seville, and Ebro, of Spain; and there are biographies of kings, e.g. Philip II; men of letters, e.g. Cervantes; and artists, e.g. Murillo. See Spanish-American War; Spanish Succession, War of the; Spanish Civil War. See also Aragon; Castile; Escorial; Granada; Moors, etc.

Spain is a country of S.W. Europe, the larger portion of the Iberian peninsula. Its area is

195,504 sq. m. The Pyrenees divide Spain from France almost completely; only to E. and W., near the coast, is communication easy between the countries. S. of the Pyrenees lies the *meseta* or Spanish plateau.

The chain of the Pyrenees is relatively narrow; barely 170 m. separate the lowland cities of Toulouse and Saragossa; half this distance is across the lowland valleys of the Ebro and the Garonne; less than a third of it lies above 3,000 ft., and the actual width of the range where it rises for 6,000 ft. above the 5,000 ft. level is barely 10 m. Affluents of the Ebro and Garonne take their rise close to the crest line within a few miles of each other at comparatively low levels, and between them rises almost sheer the mountain wall which is characterised by numerous cirques.

Coasts and Land Boundary

The S. coast along the narrows at the W. end of the Mediterranean invites communication. The Sierra Nevada and Rif heights are similar in origin; they present an abrupt slope from the sea. Cadiz and Tangier, Almeria and Melilla, similar in climate and situation, are separated by less than 170 m. of water, while Gibraltar and Ceuta are less than 20 m. apart.

The land boundary with Portugal on the S.W. follows long stretches of the four great rivers Minho, Douro, Tagus, and Guadiana, and crosses the crest lines of the intervening ridges almost at right angles; Portugal essentially comprises the lower valleys of three Spanish rivers, Douro, Tagus, and Guadiana. The N. coast on the Bay of Biscay has few indentations and no great harbours; those of Bilbao, Gijón, and Santander silt up so rapidly as to require continuous dredging. The land rises sharply to the crest of the Cantabrian Mts. and drops steeply to the deep trough of the Bay of Biscay. The N.W. coast on the Atlantic Ocean has ria (q.v.)

indentations, and ports at Ferrol, Corunna, Pontevedra, and Vigo.

The interior of the peninsula consists of the *meseta*, and the fold-mts. of the S.E. These mts., which include the Sierra Nevada and stretch from C. de la Náo to Cadiz, are broken only by the valleys of the Segura and Guadalquivir. The *meseta* is an almost square plateau with an average elevation of about 2,500 ft. It is crossed by a central line of heights parallel with the Tagus, the Sierras de Gata, Gredos, Guadarrama. Almanzor, in Sierra de Gredos, rises to 8,700 ft. It joins the highland which stretches between Burgos and Valencia and presents a scarp face parallel to the Ebro. Lower heights, the Sierra de Toledo, separate the Tagus from the Guadiana. The general tilt of the plateau is towards the W., and across it westward flow the extensive Spanish portions of the valleys of the Douro, Tagus, and Guadiana.

Climate and Vegetation

Spain experiences a curious variety of climate in which the Mediterranean type vies with the continental. The *meseta*, especially in the neighbourhood of Madrid, is the sunniest area in Europe, is the driest area W. of Russia, and suffers very severely from summer drought. Rains, falling almost entirely in the winter, are most frequent in the N.W. corner and on the mts. The clear atmosphere free from rain-clouds permits of fierce heating during the summer days and marked cooling at night, giving to the inland area large daily and annual variations of temp. Though Madrid is so far S., skating is frequently possible in Jan., while shade temp. in July may exceed 100° F. Strong winds are a feature of the plateau, blowing outwards in winter and inwards in summer; in winter these winds partially exclude the rain-bearing ones from the sea, and in summer they are so heated on crossing the plateau as to be rainless. The winter snows and the

spring rains fail to provide sufficient water to keep the rivers filled in the late summer. From Malaga along the Mediterranean coast to Barcelona extensive areas require irrigation; among them are the famous *huertas* of Murcia and Valencia; irrigation is practised near Linares and Saragossa. The slopes of the N. and W. mts. are forested with chestnut, beech, and oak at low levels, birch and mountain ash higher; the S. mts. are clothed with evergreen forest, including cork oaks and Aleppo pine.

The arid *meseta* is treeless and semi-desert heath land—thyme heaths, *tomillares*, or cistus heaths, *jarales*. The plains are steppes; that of Aragon is the *estepa ibérica*. Esparto grass grows in the S.E., wheat chiefly in the Valladolid *campos*. Olives are produced on the three plains and along the Mediterranean coast. Vines are grown in the valleys of the Minho, Douro, Guadalquivir, Segura, and Ebro; they yield sherry, Malaga, and other wines; oranges, lemons, figs, and pomgranates, as well as rice, are the products of the irrigated gardens.

Minerals and Manufactures

Spain is rich in minerals. Coal is mined near Oviedo and N. of Córdova; iron near Bilbao, W. of Córdova, S. of Oviedo, and in the Minho valley; copper at Rio Tinto, mercury at Almaden, lead and silver-lead W. of Malaga.

Spain has comparatively few manufactures. In Catalonia there are textile, chiefly cotton, factories and paper mills. Madrid has iron foundries. Toledo is famous for its sword-blades. Glass and corks are other products. The fisheries yield sardines, tunny, and cod. Sardines are caught off the N.W. coast and near Cadiz and Barcelona; tunny off the S. coast. Fruit, olive oil, and wine form the bulk of the exports; ores, minerals, and timber are sent away in smaller quantities. Machinery, petrol, raw cotton, and tobacco are imported to considerable values, and grain and timber in a lesser degree.

Rly. mileage is less than 11,000 m., of which a quarter is narrow gauge. The E. coast route goes from the French frontier to Barcelona and connects the E. ports with Algeciras; Barcelona and

Spanish flag
red, yellow,
red

Spain. Map of the republic showing the old divisions and the provinces into which the country is divided

Alicante are connected by main line with Madrid. The central route goes S. from the French frontier (San Sebastian) via the junctions of Palencia and Medina to Madrid; the Biscayan and N.W. ports are all connected with Palencia. The four valleys have rly. connexion from Spain into Portugal. The Sierra Morena mining dist. is comparatively well served by main and branch lines. The rivers are useless for navigation, as they usually flow in steep-sided narrow trenches across a rocky floor with rapids. Total road mileage is 80,000 m., of which only 4,500 m. is suitable for fast motor traffic.

The est. pop. (1947) 27,552,484, is sparse, less than 130 to the sq. m. It is densest in the N. Possibly twice as great in Roman times, it has never recovered from the incessant wars of the Middle Ages and the exhaustion that followed colonial expansion in the 16th cent. The rate of increase shows a tendency to accelerate.

The inhabitants of Spain present several very diverse types. The Castilians, inhabiting an arid and unproductive country, bore the brunt of the struggle with the

Moors, and became the dominant group. More reserved and austere than most southern peoples, proud and sensitive, they are the typical Spaniards. The Galician mountaineers are hard-working and backward in civilization. The Andalusians, deeply influenced by Roman and Moorish culture, are soft and pleasure-loving. The Catalans are an active, seafaring, commercial people.

As the result of the Civil War of 1936-39, Spain from April, 1939, was organized as a national state, with supreme authority invested in Gen. Francisco Franco, the principal leader of the nationalists during the Civil War, assisted by a cabinet of 12 ministers. There is an assembly composed of some 500 members, including the ministers, presidents of official institutions and academies, mayors of provincial towns, representatives of professional bodies and of the national syndicates or industrial organizations, and a substantial number of representatives of *Falange Española*, the only political party permitted in the state. This assembly meets at long intervals and its functions are limited to the ratification of government decrees.

The national church is that of Rome. There are nine metropolitan sees, the chief being Toledo, and more than 50 suffragan sees. The religious houses exceed 4,500 in number. Primary education is free, but despite the elaborate educational system promulgated in 1857, but never rigidly enforced, and subsequent efforts under various govts., barely 60 p.c. of the total pop. can read and write. There are 13 universities, including one in the Canary Is., and secondary schools in each prov., but the number of students is small.

Military service is compulsory, nominally for 18 years, of which two years are with the army. The civil guard, or constabulary, and the carabineros, or internal revenue and coastal guards, are recruited from the army and are under military discipline. Including these, the peace establishment numbers well over 500,000. The navy, including marines, numbers about 20,000. Attached to it is a flying service. The air force is small and includes 60 bomber and fighter aircraft.

The Canary and Balearic island groups are administratively within the Spanish state. The Spanish

colonial empire has dwindled to less than 130,000 sq. m., almost all in Africa.

PREHISTORY. The oldest human relic of prehistoric Spain is a skull of Neanderthal type from Gibraltar, although still earlier occupation may be indicated by pre-Mousterian implements. Efforts have been made to account for the Basque language still spoken in the Pyrenees by regarding it as descended from Palaeolithic speech; but the peninsula's outstanding contribution to the story of Palaeolithic Europe comprises several hundreds of mural paintings and engravings in the Aurignacian and Magdalenian caves of N. Spain. At Altamira, Castillo, Pasiega. Hornos, and elsewhere bisons and other animals are depicted with singular realism, although with a ritual purpose. Later came a more conventional style, with domesticated animals and other proofs of Neolithic origin.

Neolithic Spain was occupied by the Iberian branch of the brown Mediterranean family. Later on its mineral wealth attracted the attention of early metal-seekers from the E., and megalithic dolmens and corridor tombs mark the path of advance along the Atlantic coast northward. At Antequera an earthen mound encloses a chamber 80 ft. long, roofed with four massive capstones, the entrance being covered by another of 170 tons. At Alcalar, Los Millares, and elsewhere are tombs whose long stone-lined corridors lead into chambers with beehive roofs and side niches, as at Newgrange (*q.v.*) in Ireland.

The early metal age witnessed the introduction of cultural in-

fluences from the Aegean, and afterwards from Celtic Europe. Local styles of pottery, partly based on textile designs, were followed by one of flamboyant painted ware. Metal work, at first poor in tin, afterwards developed good bronze implements and weapons. The coming of the Phoenicians, in the wake of the Aegean mariners, is indicated by ritual and other remains. (*See* Altamira; Art, Prehistoric.)

HISTORY. It was about 1100 B.C. when the Phoenicians established their first colonies in Spain, and only a little later when the Greeks arrived. Both contented themselves with settlements along the coast, but it was otherwise with the Carthaginians who came across the Mediterranean to help the Phoenicians. They extended their authority over parts of the interior, and trade made the seaports rich and populous.

The contest between Rome and Carthage had a potent influence on the history of Spain, which about 200 B.C. passed into the possession of the Romans, whose name for it was Hispania. It was divided into provs. and governed as was the rest of the empire, receiving, with certain disadvantages inherent in the centralised and bureaucratic rule of Rome, the civilizing benefits that the city conferred upon its possessions. The people were introduced to a great system of law, were familiarised with a high culture in art and literature, and later had Christianity brought into their midst.

The Roman rule, however, was not unchallenged. About 150 B.C. a serious revolt which lasted for 10

years began, and some 70 years later there was another, the followers of Marius finding strong support in Spain. Both were crushed, as was a later rising when Julius Caesar was proprætor. For the next 450 years the history of Spain is that of the Roman empire, of which it was one of the richest and most influential parts.

The fate of Spain in the 5th century was like that of the rest of the empire. Invited by thwarted aspirants to power, the barbarians crossed the frontiers, then almost denuded of defenders, and groups of Alans, Vandals, and others were soon settled on the land. To counter this invasion Rome called upon the Visigoths, and in 414 Ataulph entered the country.

The Visigothic kingdom of Spain, established about 530 by a new effort on the part of that race, lasted for nearly 200 years. It was not a strong one, however, an elective monarchy being one cause of its weakness, and religious dissensions another. The quarrel between the Arians and believers in the orthodox faith was acute. King Recared, at a council of Toledo in 589, declared the Catholic faith to be the national religion, but the Arians were by no means crushed.

The fall of the Visigothic kingdom was due to its internal dissensions. Two rival kings were chosen and one of them looked to Africa for help. At his invitation a band of Muslims arrived in 711 and Roderic, the last Visigothic king, fell in battle. These Muslims were followed by others, and very soon Spain was in Muslim possession. Crushed by Charles Martel when

Spain. Traditional costumes, and a national sport. 1. Valencian women on a gala day. 2. A young couple from the southern provinces. 3. A bull fight in progress

they advanced into France, their hold on Spain remained. Driven from Damascus, one of their princes, Abdur Rahman, came to that country and from that time (758) the Moorish kingdom really dates. With its capital at Cordova, it covered the country as far N. as the Ebro; beyond that river the Christians lived virtually independent in the little states which were taking root and were to emerge as Castile, Leon, Aragon, Navarre, Catalonia, and Galicia.

The Moors, whose rule lasted for about 600 years, had a culture of their own, the influence of which on art and letters has not been confined to Spain. The kingdom suffered much from internal dissensions in the 9th century, but in the 10th a strong central power was established. One caliph reduced his own recalcitrant countrymen to obedience, while another drove back the Christians.

For some time the little Christian states were constantly at war with each other, but soon marriages between their ruling families led to unions of the crowns. In the 12th century Navarre and Castile were united, and later came a union between Castile and Leon. The process continued until, in the 13th century, only Castile and Aragon remained. During this time constitutional experiments in the direction of representative assemblies were made, Leon leading the way in 1020, and the towns secured self-governing privileges. The fight with the Moors continued. The task of the Christians was rendered easier by the fall of the caliphate of Cordova and its replacement by a number of practically independent states. Toledo was taken and made the Castilian capital in 1085.

The forward movement of the Christians was checked in 1086 when Alphonso of Castile was beaten in battle by the Almoravides, who had swarmed over from Africa, but the victories of the latter had one good result. In many parts the Moors and the Christians had begun to live peaceably together, even to intermarry, and this friendly feeling was hastened when the newcomers began to harry those of their own faith, who were less ferocious in their exposition of the Moslem creed. In the 12th century the Almohades superseded the Almoravides.

In the 13th century the Christian power became dominant. The kings of Leon and Castile and of Aragon carried on the war with such success that very soon only Granada was left to the Moors, and that under the suzerainty of Castile. James I of Aragon played

Spain. Map showing the distribution of the principal natural products and industries of the country

a great part in this conquest, and this was the time when Aragon obtained a national parliament and Castile a code of law that influenced European jurisprudence. A civil war in Castile disturbed the progress of the 14th century. Two rivals, Peter the Cruel and Henry, an illegitimate half-brother, were fighting for the crown, and France and England seized the opportunity to carry their struggle into Spain. Henry gained the upper hand, but under his successors the country was for a century in a state of anarchy.

The great period of Spanish history begins with the accession of Isabella to the throne of Castile in 1474. She was married to Ferdinand, who, in 1479, became king of Aragon, this uniting the two remaining Christian kingdoms. Under this firm rule order and prosperity were restored, preparing the way for a fresh campaign against the Moors. In 1492 their last stronghold, Granada, was captured, and in the same year Columbus discovered America. Spaniards crossed the Atlantic to take possession of the new lands, the wealth of which formed an almost inexhaustible treasure house.

In 1516 Spain passed under the rule of Charles, afterwards the emperor Charles V, and thus was incorporated in the Hapsburg dominions. It was separated from Austria on his abdication in 1556, but as left to his son, Philip II, the empire was of immense extent. It included the rich Netherlands, Sicily, and much of Italy; and the southern part of N. America—not only Mexico but also a large part

of what is now the U.S.A. S. America had been divided by the pope between Spain and Portugal, but when Philip was proclaimed king of Portugal in 1580 the whole of that continent became Spanish. Possessions in Africa and in the East complete the tale.

The decay of Spain dates from the time of Philip. He became involved in the war with England which led to the Armada, while the Netherlands broke into revolt and the northern states declared themselves independent. The wealth of America brought about a general disinclination to work, unwise economic laws added to the confusion, and the provinces and the towns lost most of their ancient privileges. The Moriscos were expelled in 1609, while wars drained the country's resources. Spain fought in the Thirty Years' War, continuing the struggle with France until 1659. In 1640 Portugal again became independent.

In 1665 Charles II became king. After an inglorious reign he died in 1700, when the elaborate arrangements made by the rulers of Europe for the partition of his lands were not carried out. Instead, Louis XIV claimed all for his grandson and the War of the Spanish Succession was fought. It ended in the accession of the French prince as Philip V, but Spain's possessions in Italy and the Netherlands were lost.

Under the Bourbon rulers Spain made an attempt to recover her lost glories, and the reign of Charles III (1759-88) was one of reforms at home and abroad. The policy of hostility to France was

abandoned and the two powers were found acting together in almost all the wars of the century. The alliance continued during the early years of the French Revolution, but it was disastrous. Napoleon turned out the Spanish king Ferdinand VII, in favour of his brother José Bonaparte, to which the Spaniards replied by rising in revolt and with the aid of Great Britain carrying on the Peninsular War. The Bourbons were restored in 1814.

Early in the 19th century Spain lost her American colonies, which, during the reign of Ferdinand VII, formed themselves into independent republics. On the king's death in 1833, a civil war broke out between Ferdinand's daughter Isabella and her uncle Don Carlos, the former securing the throne after the first Carlist War. Meanwhile, constitutional privileges had been granted, but unrest continued and for five years (1868-73) the country was in a state of anarchy.

In 1875 Isabella's son, Alphonso XII, was proclaimed king. In 1886, his posthumous son, Alphonso XIII, succeeded. In 1898 Spain and the U.S.A. came to blows, the end being the loss of Cuba and the Philippines. The early years of the 20th century were marked by disorder caused by anarchists and others, events being the riots at Barcelona in 1909 and trouble leading to martial law everywhere in 1911. In 1910-11 there was a quarrel with the Vatican.

The First Great War

Spain remained neutral in the First Great War, despite German efforts to induce her to oppose the Allies. The attacks made by German submarines upon Spanish merchant vessels, 1917-18, often within Spanish territorial waters, led the Spanish govt. to protest.

Meanwhile domestic affairs continued very unsettled, ministry succeeding ministry in bewildering succession. In 1916 there were serious riots and martial law was proclaimed, Barcelona being again the storm centre.

A serious military reverse suffered by the Spanish troops in July, 1921, during a rising in Morocco, caused an acute political crisis, aggravated by growing unrest throughout the country. The insistent demand from press and parliament for an inquiry into the responsibilities for the military disaster brought the army into conflict with the politicians, culminating in a military revolt in Sept., 1923, led by Gen. Primo de

Rivera. Constitutional government was suppressed, and replaced by military rule in the form of a "directorate" with Rivera as prime minister. The dictatorship fell after nearly seven years of inefficient rule, and a cabinet of politicians, charged with the task of preparing the country for a return to constitutional govt., was formed. The first important step was the holding of municipal elections on April 12, 1931, which gave the victory to a coalition of parties opposed to the monarchy. Two days later the king left the country and the republic was proclaimed.

The Spanish Republic

The new régime was disturbed from the beginning by revolts and strikes fostered by extremists from the right and the left. The disestablishment of the Church, the expulsion of the Jesuits, and other anti-clerical measures roused the hostility of the Church and of the moderate elements supporting the republic. A "popular front" govt. was formed in Feb., 1936, as a result of an election in which the Liberals won 162, the Socialists 94, the Communists 16 out of a total of 470 seats. Fascists and monarchists, and their supporters in the armed forces, took that as a challenge, and embarked in a campaign of disruption and insubordination which led to the outbreak of the Civil War five months later. The war lasted nearly three years, ending when the last republican government in Madrid surrendered to the nationalists. During the Second Great War Spain was again neutral, though benevolent towards the Axis. Repeated refusals by the United Nations to admit Spain to membership during Franco's régime had the effect of making the dictator's position stronger rather than weaker.

aga, 1942; Politics, Economics and Men of Modern Spain (1808-1946), A. Ramos Oliveira, 1946; Ambassador on Special Mission, Viscount Templewood, 1946.

LANGUAGE AND LITERATURE.

When speaking of the Spanish language one refers exclusively to the Castilian, which is the official language in Spain and is spoken today by twenty nations. The other languages spoken in Spain are regional in character and use. The chief of these is Catalan, with its variations of Majorcan and Valencian, which has its own literature of no mean merit.

Castilian is derived from popular Latin. The majority of writers maintain that the Goths exercised hardly any influence on its formation, since they can find in it only about 100 Gothic words. The corruption of Latin began during the Roman domination, the language becoming mixed with that then spoken in central Spain by the Celtiberians. The transformation continued during the Visigothic period, and when the Arab invasion took place, those Spaniards who preferred independence and took refuge in the mountains of the N. carried with them a half-formed language, destined to become general. The original Castilian enriched itself considerably from the Arabic during the centuries of the Reconquest.

The Castilian Epics

While the intellectual movement among the Jews and Arabs in the first three centuries of the Reconquest influenced the culture of the Spaniards, Castilian literature began with epic poetry. Religious and warlike poems were composed, celebrating miraculous or heroic deeds, and these were popularised by the travelling bards. Thus the first two works of importance in the middle of the 12th century are a religious drama, *The Mystery of the Magian Kings*, and the epic, *The Poem of the Cid*, which necessarily imply a considerable previous development of the poetic art. The former is noteworthy for the vivacity of its dialogue and dramatic action. *The Poem of the Cid* comprises 3,729 verses; there are gaps in it, but even so it is a most beautiful work which set an ideal for humanity. It is the greatest of Castilian epic poems. Of the 12th and early 13th centuries there are also preserved a number of romances, such as *The Deeds of Don Sancho II of Castile*, and *The Book of Apollonius*.

Gonzalo de Berceo was a poet of great vigour and originality;

although most of his works that have reached us deal with religious subjects, he handles them with novelty and in a simple yet majestic manner. His chief work, the *Life of S. Oria* written towards the end of his life is full of mystic inspiration, revealing both genius and culture. Shortly before the inauguration of didactic prose by Alphonso X, the Poem of Fernán Gonzalez was composed. This work marks the transition from the popular to the artistic epic.

The Great Conquest of Overseas belongs to the 13th century, about the end of the reign of Sancho IV. The king is credited, but not very definitely, with the beginning of the *History of the Knight of God* who was Named Cifar, the precursor in Spain of the books of knight-errantry, in which one can already see the gay and romantic characteristics which were to develop later in Castilian literature.

14th and 15th Century Writings

In the 14th century two figures stand out with great brilliance. The first is Juan Ruiz, whose genius revolutionised ideas, poetry, substance, and methods. The other was the Infante Juan Manuel, grandson of Ferdinand III, who, among other works, mostly didactic, wrote a masterpiece, *The Book of the Deeds of Count Lucanor*. It is written in excellent prose, and there is a summary in verse at the end of each chapter. Other notable works of the 14th century are *The Song of Rodrigo*, attributed to Esteban de Gormaz, which inspired the great work of Corneille and many others based on the doings of the Cid, the *Moral Proverbs of the Jew Sem Tob* (Santos de Carrión), *The Dance of Death*, supposed to be by the same author, and the works of Pedro López de Ayala, the most noteworthy of which are *The Great Chronicle of Spain*, and the poem, *The Palace Rhyme*. Lopez de Ayala was the first to introduce Italian literature to Spain, by translating the works of Guido de Colonna and Boccaccio.

Conspicuous writers of the 15th century were E. de Villena, who composed *The Art of Rhyming* and many other didactic works, among them his *Treatise on Divination* and the *Magic Art*, which earned for him the name of sorcerer and the destruction of his library by order of John II; Juan Alonso de Baena, with his *Song-book of Baena*; the Marquess of Santillana with his famous *Serranillas* and his poems; Juan de Mena with *The Labyrinth of Fortune*; Fernán

Pérez de Guzmán with his *Praises of the Illustrious Men of Spain*, and his *Sea of Histories*; Ruy González de Clavijo with his *History of the Great Tamerlane*; Juan de Dueñas with his *Coplas del Provincial*; Hernando del Pulgar with his *Mingo Revulgo*, a first and intense manifestation of satire; Gomez Manrique with his *Battle of Love* and other celebrated works; and Jorge Manrique with his famous *Coplas*, or verses, on the death of his father, which is a gem of Spanish literature.

For more than 150 years, from 1477, Spanish literature attained its highest perfection. During that time each branch was cultivated separately. The Spanish theatre was initiated with the famous tragi-comedy Calixto and Melibea, commonly known as *La Celestina*, of Fernando de Rojas, and with the works of Juan de la Encina and Lope de Rueda, but it did not acquire its definite form and superb development until Lope de Vega, who may be called the founder, and of his works about 470 are extant. It was continued in that time by Tirso de Molina, Juan Ruiz Alarcón, Calderón, Moreto, and Rojas Zorrilla, to mention the most notable.

Fiction had an initiator in Hurtado de Mendoza with *El Lazarillo del Tormes* (The Beggar of the Tormes) and culminated in Cervantes with *Don Quixote* and his *Exemplary Novels*. This branch was cultivated by Quevedo, Velez de Guevara, Mateo Alemán, and others. Lyric poetry shone with countless good poets, including, besides Lope and Calderón, Gongora and the brothers Argensola, Herrera, Garcilaso, Fray Luis de León, Alcázar, and many others; history with Zurita, Mariana, and Morales; epic poetry with Ercilla's *The Araucana*, celebrating the prowess of the warlike Indians of Chile; and mystic poetry with S. Teresa de Jesús, Fray Luis de Granada, San Juan de la Cruz, and Malón de Chaisde.

Eighteenth-Century Decline

Two other great writers, Saavedra Fajardo and Baltasar Gracián, appear before the end of the 17th century. From this point onwards all the branches of literature seemed to waste away. For the best part of the 18th century only Feijóo, critic and scholar, stands out. After him came Jovellanos and Cadalso, the poet Meléndez Valdés, the fabulists Iriarte and Samaniego. The theatre, which had fallen into decadence, was revived and revolutionised by the plays of Leandro F. de Moratín and Ramón de la Cruz.

At the beginning of the 19th century two great poets appeared, Quintana and Gallego. Then came the romantic period, which in drama was cultivated by Martínez de la Rosa, the duke of Rivas, García Gutiérrez, Hartzenbusch, and José Zorrilla, and in poetry by the last named and by Espronceda, and Arolas. The generation that followed was intermediate between romanticism and realism. It included the dramatists Ventura de la Vega, Bretón de los Herreros, Tamayo y Baus, and Adelardo López de Ayala. At about this time Campoamor began his philosophical, epigrammatic and humorous poems, and Bécquer composed his *Rimas*.

Among the prose writers the most brilliant in the early part of the century was Larra (Figaro). Shortly afterwards came the generation of great novelists, which includes Pedro A. de Alarcón, Pereda, Valera, and Pérez Galdós.

Twentieth-Century Revival

From the beginning of the 20th century there was a revival in all fields of Spanish literature, which, however, came abruptly to an end in 1936, with the outbreak of the Civil War. The outstanding novelists of this period were Pérez Galdós, Valle Inclán, Palacio Valdés, Emilia Pardo Bazán, Blasco Ibáñez, Pío Baroja, and Ramón Pérez de Ayala. The theatre, which for nearly 20 years up to the close of the 19th century had been dominated by the sensational plays of Echegaray, was revolutionised by Jacinto Benavente, who wrote such masterpieces as *Los Intereses Creados* and *La Malquerida*. The stage was also cultivated by the brothers Alvarez Quintero, who produced plays of great vitality and colour, Marquina with historical dramas, Linares Rivas and Martínez Sierra with high comedy, and Perez Galdós with great plays such as *La Loca de la Casa* and *Mariucha*. Light comedy had its masters in Ricardo de la Vega and Javier de Burgos. Lyric poetry was revived by Rubén Darío, Villaspesa, the brothers Machado, and others. Among the poets of modern tendencies the outstanding figures were García Lorca, Pedro Salinas, and Rafael Alberti.

Among the essayists and philosophical writers, Unamuno and Ortega y Gasset are the most prominent. In the domains of erudition and literary criticism the greatest figure of the period was Menéndez Pelayo. His work was successfully continued by Menéndez

dez Pidal and J. Martínez Ruiz (Azorin).

ART. There are three characteristics of Spanish painting. The subjects are almost always devotional; the colour schemes invariably have a somewhat sombre hue; the school, compared with that of other countries, is late. It did not attain high importance until the latter part of the 16th century. Furthermore, the Spanish painters were in many instances craftsmen, and designed fine work in gold or wrought iron, in carved wood, in stone, and even in architecture, as well as in painting.

The earliest days of Spanish graphic art were influenced by Jan Van Eyck, who visited Spain in 1428, and impressed his characteristics upon the artists of the day. Gothic art in Spain was much connected with mural decoration. There were various schools, having little connexion with one another, existing in different divisions of the country, Castile, Andalusia, Valencia, etc. Notable men of this period were Alexo Fernandez (fl. 1506-25), Rincón (fl. c. 1500), Borgoña (d. 1533), noted also for his sculpture in wood and stone, and Pedro Berruguete (d. c. 1503). In the early 16th century Italian influence can be discerned, and Alonso Berruguete (1480-1561), the son of Pedro, was one of its most notable exponents. His work can be studied specially at Valladolid. Other artists of this period were Luis de Morales (1509-86), the painter of altar-pieces under Philip II, Velasco of Toledo (fl. 1580), and Luis de Vargas, a painter of Seville (1502-68). A little later Venetian influence became paramount, and the representative artist was Juan Fernandez Navarrete (c. 1526-79), the dumb painter known as El Mudo.

The great period starts with the Cretan, Domenico Theotocopuli, generally known as El Greco. The supreme painter of Spain was Velazquez, an artist of incomparable skill, the triumphant painter of life and character. Murillo was the leading painter for the Church, painting in monastic houses and

ecclesiastical establishments, and producing many altar-pieces. These pictures are rich in quality, deep in shade or strong in light, and glow with brilliant colour, but his greatest works were his genre pictures, frank expressions of the life of the people.

Zurbarán, the peasant painter, represents the asceticism of Spain, and what might be termed its indifference to actual beauty. No one ever painted monks as he did. He ignored idealism and had a passion for the actual and real. Quite different was Ribera. He was a fine draughtsman, a dramatic painter, full of Italian feeling, dexterous in the management of colour, and revelling in intense shadows, always having before him a decorative ideal.

Francisco de Goya, the satirist and portrait painter, differing from all who had preceded him, scoffed at ecclesiastical life, and was bitter in his satire respecting it and court ceremonial, able, however, to paint court groups with extreme skill, to produce wonderful portraits, audacious perhaps in draughtsmanship, but magical in effect of colour. He was a great decorator, and his balcony scenes in the church of San Antonio de la Florida, irreverent though they may be, are marvellous works.

Later Painters

Of the modern school, Mariano Fortuny came from Barcelona. He was a painter of beauty, strongly attracted by objects of colour, rare textures, Arab mosaics, weapons, and tapestry. Few could paint with such skill a wedding group, the interior of a sacristy, the vestments of a priest, the gorgeous colour of a room, the imposing ceremonial of a court.

Sorolla y Bastida (d. 1923) was a great painter of sunlight, of the sea, of vivid movement; his work was characterised by brilliant execution and glowing colour. Ignacio Zuloaga (d. 1946) was a realist, who dipped his brush in blazing colours and, regardless of the ordinary canons of beauty, determined to present truth in all its stern austerity.

The medieval sculpture of Spain was strongly influenced by that of the French, of whom the native artists were apt pupils, as shown by the figures on the W. front of the cathedral of Santiago de Compostela, designed about 1188 by Master Mateo, by the 13th century statuary in Tarragona cathedral, and that of the 14th century at Gerona. In the 15th century German, and in the 16th Italian influence appear. The great Spanish

sculptors of the Renaissance were Alonso Berruguete and Gaspar Becerra (1520-70).

The most characteristic form of sculpture is the wood-carving of the 16th and 17th centuries, which is the glory of many Spanish churches, especially the retables and religious figures called *pasos*. P. de Vigarni, J. M. Montañés (d. 1649), and Alonso Cano (1600-67) were notable masters of this art. Later statuary, partly through the discouragement of the study of the nude, decayed. S. Churriguera (1650-1725) founded a tasteless baroque style, overloaded with ornament. Late in the 19th century a revival began in Catalonia.

Spanish architecture was moulded by two powerful influences, the Moorish and the French. Gothic developed late, and shows little independence, although before the middle of the 13th century three magnificent cathedrals were built, Burgos, Leon, and above all Toledo. The flamboyant style developed early in the 16th century into the national plateresque, or silversmiths' style, which combines the rich conventional decoration derived from the Moors with Renaissance features. Ornament is often concentrated on the portals. Later Renaissance work developed on national lines, the heavy Italian cornice being replaced by the open gallery at the top of the wall.

The minor arts were brought to a high standard in the great age of Spain. The production of lustrous ware and of coloured and stamped tiles was learnt from the Moors, but perhaps the finest work was done in metal. The churches of few if any countries have such exquisite goldsmiths' and silversmiths' work, jewelry set in silver filigree, tabernacles, silver-plated iron screens, candelabra, and monstrances. Some of the best work was done by the families of Arfe, of Flemish origin (15th and 16th centuries), at Córdoba and Seville, and of Becerril (16th century) at Cuenca.

Spalato. This seaport on the Dalmatian coast of Yugoslavia is generally known as Split (*q.v.*)

Spalding. Market town and urban dist. in the Holland div. of Lincs, England. It stands on the Welland, 14m. S.S.W. of Boston, and is a rly. junction. The principal building is the parish church of SS. Mary and Nicholas, a 13th century building restored in the

Spalding arms

19th century. It has four aisles and a notable lady chapel. Other buildings include the corn exchange and the Johnson hospital. There is a grammar school, founded in 1567, but occupying a modern building, and remains of a priory. Ayscoughfee Hall, dating from 1420, was the residence of Maurice Johnson. An agricultural and horticultural centre, Spalding has a trade along the river. Other industries are breweries, flour mills, and sawmills, while tractors and agricultural implements are made. Around the town is reclaimed fenland on which bulbs are grown. In Spalding in 1710 Maurice Johnson founded the Gentlemen's Society, a club of which Addison, Newton, and Pope were members; it still exists. The Romans built a bridge here, but the place grew up around a priory and until the Reformation was under the authority of the prior. Market day, Tues. Pop. 13,500.

Span. Linear measure, half a cubit. One of the natural measures, it was the stretch of the fully opened hand from little finger to thumb (9 or 10 ins.).

Spandau. Borough of Berlin, Germany, situated about the junction of the Havel and the Spree, 8 m. W. of the city centre. Before the First Great War it was a garrison town, having also an arsenal and factories for the manufacture of arms and ammunition. Some of these were later converted into plants making machines and motor vehicles. The chief building was the 16th century citadel, and the Julius tower therein was selected to hold £6,000,000 of gold exacted from France in 1871. Here also was the German academy of gymnastics. Spandau was made a municipality in 1232.

and later the electors of Brandenburg had a residence here. It was taken by the Swedes in 1635 and by the French in 1806. There was heavy bombing in the Second Great War, after which it lay in the British-occupied sector of Berlin. Pop. approx. 100,000.

Spandrel. In architecture, the space between the extrados or outer curve of an arch, a horizontal line from the crown of the arch, and a vertical line from its springing. Where there are two adjoining

Spandrel in architecture

arches the spandrel will be the space between their extradoses, the uppermost limit being a line connecting their crowns. It is a favourite place for sculptural and other decoration. See Arch.

Spaniards Inn, THE. Tavern at the junction of Spaniards Road and Hampstead Lane, Hampstead Heath, London, N.W. The Gordon rioters were delayed here while on their way to destroy Lord Mansfield's house at Ken Wood, 1780. The inn dates from the 18th century. Spaniards Road, overlooking the Heath, is a popular promenade. See Ken Wood.

Spaniel (old Fr. *espagneul*, Spanish). Group of dogs, distinguished by a wide short skull, a high forehead, a heavy build, and large pendent ears. Most have thick, long, and silky hair. The three main classes are land, water, and toy spaniels. In the wider sense of the word, spaniels include setters, retrievers, Newfoundlands, St. Bernards, and probably poodles. Of the other breeds, the Clumber spaniel takes its name from a seat of the duke of Newcastle, who introduced it to Great Britain from France. It is a large, heavy animal,

with a dense coat of white and lemon-coloured hair, and makes a good dog with guns.

The cocker spaniel is only half the size, with a longer head, and silky wavy hair. It derives its name from its use in woodcock shooting, and will drive game from low coverts and hedges. The field spaniel is a long-bodied, short-legged type, formerly black in colour, but now varied. It is a favourite show dog, and the practice of breeding for points has tended to diminish its usefulness. It is an active and lively dog, and works well with guns. The water spaniel is an Irish breed, now seldom found pure. It is a large dog with splay feet and a curly coat of rather oily hair, and has a top-knot on the head, but the face is usually rather bare. It is used for retrieving game from water, and is a strong and ready swimmer.

The various toy spaniels are kept purely as pets. One of the most famous is the King Charles

Spaniel. An English springer, a variety of this sporting breed

(q.v.). The Blenheim spaniel is somewhat similar, but its colour is white and tan with a blaze of white on the head. It should have a round head with upturned nose and a very short muzzle, and the ears should touch the ground. The Prince Charles and the ruby spaniel differ only in colour, the former being black, white, and tan, and the latter a rich red.

Pekinese dogs were imported from China late in the 19th century, and are much in demand as pets. They often weigh less than four pounds, and have very short muzzles and long hair. The tail is carried curled over the right side of the back, and a reddish fawn is the favourite colour. See Dogs colour plate.

Spanish-American War. Conflict between the U.S.A. and Spain, 1898. The proximity of Cuba to the U.S.A. had caused that power

Spandau, Germany. The Julius Tower, in which was deposited the gold exacted from France in 1871

to view with misgiving the misgovernment of Spain. Matters came to a crisis after the rising of 1895, the crushing of which reduced Cuba to starvation and ruin. Friendly suggestions from the U.S.A. passed unnoticed, the rights of American citizens were ignored, and in 1897 the U.S.A. began to make serious preparations for intervention. On Feb. 15, 1898, the U.S. battleship Maine was blown up in Havana Harbour, according to investigators by a mine, and on March 11 the U.S. army mobilised. Congress declared the independence of Cuba, April 11, and Spain declared war April 24.

The naval campaign was localised to the Philippine Islands and Cuba. In the former Admiral Dewey destroyed the Spanish fleet under Admiral Montojo at the battle of Manila Bay (q.v.), May 1; while off Cuba Cervera's fleet was

blockaded in Santiago Bay by Admiral Sampson until July 3, when the Spaniards slipped out, were chased, and totally defeated. In the meantime, military operations had begun in Cuba with the landing of 16,000 men of the U.S. army. Aided by the Cubans, the Americans attacked Santiago, which capitulated July 16. Eleven days later the Americans landed at Puerto Rico, and the end of the war came with a combined naval and military attack on Manila, Aug. 13, the Spanish forces, some 13,000, capitulating next day. Peace was concluded in Paris, Dec. 10. Spain relinquished Cuba and in return for £4,000,000 ceded the Philippines, Puerto Rico, and Guam to the U.S.A. See Cuba; Philippine Islands; Spain; United States (History). Consult History of the Spanish-American War, R. Titherington, 1900.

result despite the slight preponderance of right plus centre votes over left votes as a mandate for social revolution, the right parties embarked upon a series of acts of provocation in order to embarrass the new govt. The spring and early summer of 1936 was a period of violence, strikes, lock-outs, and street-fights. The former ruling class began preparations for a full-scale revolt. The great landowners, the aristocracy, the industrialists, the financiers, the higher army officers, and the Church all saw their vital interests threatened by the general unrest, and determined to defend them by any means. Propaganda campaigns by both sides became intense.

The spark which set light to the powder-magazine was the murder by right supporters of Lt. Castillo on the night of July 12-13, and the reprisal murder of the right leader Calvo Sotelo next day. Calvo Sotelo, it was afterwards disclosed, was political leader-designate of the movement to overthrow the govt. by force. The military leader was Gen. Mola, commanding in Navarro and Burgos, who had ordered his fellow-conspirators in the army to be ready and at their posts on July 15. They were Queipo de Llano in Andalusia, Cabanellas in Saragossa, Saliquet in Valladolid, González Carrasco in Valencia, Goded in Catalonia, Fanjul in Madrid, and Franco in Spanish Morocco. A message from Mola informed the Falangist leader José Antonio Primo de Rivera that he had fixed the rising for July 18, 19, and 20. Gen. Franco publicly announced the insurrection on July 17-18.

SPANISH CIVIL WAR, 1936-1939

Charles Duff, Editor, *The War in Spain*

This account of the worst civil war in modern Spain begins with the results of the Feb., 1936, election and concludes with the establishment in power of the Franco regime. See also Franco, F.; Mola, E.; Primo de Rivera; Spain: History

The Spanish Civil War began with a military insurrection in Spanish Morocco on July 17, 1936, in metropolitan Spain on July 18. The permanent unrest in Spain arises from the fact that the Spanish people have not progressed beyond the first phase of democratic evolution. The end of the monarchy, with Alfonso XIII's departure from Spain and the proclamation of the second republic (April 14, 1931), marked a step towards social revolution. Parl. elections held on Feb. 16, 1936, resulted in

the return of 265 members of "left" sympathy (of whom 238 belonged to the "popular front" parties—136 left Republicans, 87 Socialists, 15 Communists), who polled 4,523,981 votes; 142 members of "right" sympathy, including Basque Nationalists, polling 4,128,092 votes; 66 members of "centre" sympathy, polling 449,320 votes. Not one representative of the Falange (extreme right) party was elected. The popular front parties, who took office, interpreting the election

Spanish Civil War. Pictures showing the plight of civilians, chief victims of civil war. 1. Refugees fleeing from their homes in the centre of Teruel. 2. Boats bringing refugees to the French bank of the Bidassoa, whence they watch the burning of their homes in Irun. 3. Last militiamen of Catalonia arriving in France by the passes over the Pyrenees. On the road they pass a blackboard ironically inviting those who wish to join Franco

On the 18th all the other generals, and Admiral Salas in command of the fleet, set their forces in action. The insurgents (who called their rebellion a great national movement) hoped that, because of their command of all national forces plus the element of surprise and, not least, because of the governmental confusion and the lack of unity among its supporters, that their movement would quickly succeed. Mola had assured himself of support by the majority of army officers, of the fleet, the civil guards, two Moroccan divs., the Foreign Legion, the Falangists, and the fanatical *Requetés* or Carlist-Monarchists. He had, furthermore, assurances of help from the dictators of Germany, Italy, and Portugal; and he relied upon the moral support of the Church. But to the surprise of the insurgents there was an immediate and spontaneous rising of the Spanish people in defence of the govt. In the first days and weeks of the struggle, they fought trained and well-equipped troops with any sort of weapons, and with astonishing

success, sacrificing themselves with great courage against apparently impossible odds. The generals' revolt had brought a measure of unity and collaboration to the govt. and its supporters. So great and effective was this counter-movement that the carefully planned military rebellion was defeated outright in the Basque provs., in the whole of Catalonia with its important capital Barcelona, in all the Mediterranean provs. round to Málaga, in Asturias, in Madrid and the centre of Spain, and in the island of Minorca with its important naval base Port Mahon. The rebellion succeeded in Morocco, in Majorca, in western Spain from Galicia to near Málaga, including Seville and Cadiz; and in the Canary Is. Spain was now divided into two as yet not sharply divided zones.

Having succeeded in Morocco, Franco moved to the mainland, bringing with him his Moorish troops and the *Tercio* or Foreign Legion Mola, meanwhile, pressing forward towards the capital with four columns, made the famous

remark that in Madrid he had a "fifth column" of supporters. These were the two outstanding generals on the rebel side. The death of Mola in an air crash on June 3, 1937, left Franco in undisputed command of the national movement. The war had everywhere been fought and continued to be fought with great ferocity on both sides.

On July 28, four Italian Caproni warplanes with Italian air force crews landed inadvertently in French Morocco. Interviewed by Marcel Peyrouton, the French high commissioner, they declared that they had received instructions on July 15 to report to the Nationalists in Spanish Morocco. Italian and German help to the Nationalists increased, and Great Britain, seeing in this active intervention a threat to European peace, on Aug. 4 suggested to France the negotiation of a non-intervention agreement in which the U.K., Germany, France, Italy, and Portugal should participate. On Aug. 25 the U.S.S.R. announced its adherence to the agreement reached on Aug. 15 by the U.K. and France. Although both Germany and Italy agreed to it, they did not observe it, with the result that the U.S.S.R. considered itself free to send arms to the Spanish govt. of Largo Caballero. These arms began to arrive in Spain towards the end of Oct., 1936. Thus, what had begun as a military revolt and developed into a civil war, now took on the complexion of a civil war plus an ideological struggle with international complications. Spain became a cock-pit in which one side had the active support of Nazi Germany and Fascist Italy, and the other received help from the U.S.S.R., from Mexico, and also in the form of international brigades recruited from nationals of many countries which entered

the struggle at Madrid in Nov. when the defenders were severely pressed. The international brigades never reached a total of 50,000 men and were disbanded in Oct., 1938, by the govt. of Dr. Negrín—a gesture of good faith which the Spanish premier hoped would persuade France and the U.K. to press for the withdrawal of the considerable German and Italian forces, which, despite denials by their govts., were fighting on the side of the Nationalists.

Three Phases of the Conflict

The opening phase in the war, from July to Sept., 1936, was a military rebellion countered by a mass rising. It was followed from Oct., 1936, to Nov., 1938, by a period of irregular or quasi-guerrilla fighting changing to full-scale regular warfare in which forces of almost 1,000,000 men on each side became locked on a front of about 1,000 miles in a life and death struggle. Outstanding military incidents were the successful defence by the rebels of the Alcázar fortress at Toledo (July 18–Sept. 27, 1936); the taking of Málaga (Feb. 8, 1937) by a mixed force of rebels and Italian troops; the campaign (May–June, 1937) resulting in the capture of the Basque provs. by a Nationalist force, largely Italian and assisted by the German Condor legion (air force with Franco); the total destruction by high explosive and incendiary bombs of Guernica, the historical little Basque capital (April 26, 1937) by Condor aircraft under the command of the German Gen. Sperle (who afterwards directed Luftwaffe attacks on London and other English cities); the defeat and rout of Italian forces at Guadalajara (March 12, 1937) by a govt. force commanded by Gen. Miaja; the capture of Teruel (Jan. 17, 1938) by govt. forces, and its abandonment by them (Feb. 22, 1938) after one of the most cruel struggles of the war; the brilliant crossing of the River Ebro (July 25, 1938) by govt. forces; the Nationalist drive to the Mediterranean, reached by Franco's forces at Vinaroz on April 15, 1938, a move which cut off Catalonia from the rest of government Spain. Four days later Franco broadcast from Saragossa: "The war is now over. These are the days of conquest." The war was to last almost another year, for the govt. continued to defend Madrid successfully.

During the second phase of the war, Spain became sharply divided into two zones, Nationalist and Loyalist. The Nationalist zone,

being the better for wheat-production and having behind it the Portuguese supply base, did not suffer from lack of food, and the govt. on the whole refrained from bombing its civilian populations. By the winter of 1938, and until the end, the Loyalist zone was reduced to a state of semi-starvation by the Nationalist blockade. Its civil population was harassed by unrestrained and for the most part indiscriminate bombing by German and Italian aircraft.

Phase 3 of this fratricidal strife was from Nov., 1938, until the end, a period during which Franco's forces, in many places victorious and now well equipped, gave proof that he had reason when he said to a newspaper correspondent: "We shall win because we have most material."

The Nationalists Victorious

Barcelona fell to the Nationalists on Jan. 26, 1939, and Franco's men advanced rapidly northwards through Catalonia, driving before them the remainder of the govt.'s forces in that area, severely handicapped in fighting the rearguard battle by nearly half a million civilian fugitives who cluttered the roads until they reached the French frontier and crossed into France. The war in Catalonia ended on Feb. 9, 1939, the Nationalist offensive which achieved the conquest of this area being almost entirely an Italian military operation.

In Madrid the defence still held. Thither Negrín flew on the fall of Catalonia, his object being to reorganize the govt.'s forces in the central zone and continue resistance until the arrival of a substantial supply of expected arms. The morale of the Madrileños and of the population in the central zone remained unshaken by their own sufferings or by the military defeats on other fronts. Experts, including many foreign observers, were of opinion that the capital would still be able to hold out for several months.

When Negrín arrived in Madrid, however, on Feb. 10, 1939, he found that two groups, one influenced by the elderly Socialist Don Julian Besteiro, the other by Col. Sigismundo Casado (commanding the Madrid army), had joined forces with the object of negotiating peace with Franco. Casado's view was that Franco would not negotiate with the Socialist leader Negrín, and he assured British officials in Madrid that, as a soldier, he could get much more out of Franco: a military dictatorship excluding all Communist influence,

he thought, would be the best to negotiate peace. While Casado was winning support for this idea, Negrín, apostle of continued resistance, announced that he would broadcast an appeal to the nation on March 5. Casado and Besteiro and their supporters (calling themselves a council of national defence) forthwith issued a manifesto opposing the policy of continued resistance, and the two leaders made speeches, Casado's directed to "the Spaniards on the other side of the trenches" appealing for an "honourable peace without reprisals." The effect of the manifesto and speeches was to split the govt. forces, and cause dismay and despondency in the central zone, as a corollary of which the govt. fleet left Cartagena on March 4 for N. Africa—an act of desertion. A series of deeply tragic incidents followed. Men who had since July, 1936, fought beside each other in the defence of the capital now fought with one another, those favouring resistance against those who wished the war to end.

Franco disillusioned the party who believed in the theory that he would negotiate with a soldier but not with Negrín. The Nationalist leader announced categorically that his terms were unconditional surrender. By this time the morale of the people and of the troops, and with it the military position of Madrid, were so weakened that further resistance to the overwhelming Nationalist armies was useless, and Madrid surrendered on March 28, 1939.

The Aftermath

Fighting had everywhere ceased, and the weary and hungry soldiers of the govt.'s army were in many places already filling the roads on the way to their homes. So ended the most bitter and devastating civil war Spain had ever known.

Madrid was occupied by Franco's forces on March 30. Nationalist military tribunals were set up and in the months which followed thousands who had supported the government cause were tried for "rebellion," and sentenced to death or given long terms of imprisonment. How many suffered in this way cannot be computed, but in the summer of 1948 it was estimated that there were still approx. 100,000 political prisoners in the jails, and military tribunals were still functioning. In the year 1947 the number executed for activities against the regime was officially stated to be 252.

The first result of the civil war was the consolidation of the total-

tarian regime which Franco had established in the Nationalist zone. He himself became *El Caudillo*, the leader, a term equivalent to *Der Führer* of Germany and *Il Duce* of Italy. The new Spanish regime was an adaptation of Italian Fascism and German National Socialism, based on the 26 points of the programme of the Falange, or Spanish Fascist party, which, from small beginnings had grown under Franco's leadership to number, it was claimed in 1942, some three million members.

Steer, 1938; *Homage to Catalonia*, G. Orwell, 1938; *Life and Death of the Spanish Republic*, H. Buckley, 1940.

Spanish Fly (*Lytta vesicatoria*). Really a green beetle, from which the pharmaceutical product cantharidin is prepared. See *Blister Beetle*; *Cantharides*.

Spanish Main. Name formerly given to the Spanish possessions on the coast of the American mainland from the mouth of the Orinoco to Yucatan, and often loosely used as a synonym for the neighbouring Caribbean Sea.

Spanish Reformed Church. Protestant Church in Spain. It arose in Seville in 1871, spread to other parts of Spain and to Portugal, and applied to the Church of England in 1878 for the consecration of a bishop. Plunket, archbishop of Dublin, and two bishops then consecrated the former R.C. priest, J. Cabrera. The Spanish Reformed Church used a liturgy composed of materials taken from the Anglican Prayer Book and the ancient Mozarabic liturgy.

Spanish Succession. WAR OF THE. European war, fought 1702-14, by France, Spain, and Bavaria, against Austria, Prussia, Great Britain, Holland, Denmark, and Portugal. Savoy fought first for France and from 1703 for the coalition.

By the partition treaties of 1698 and 1700 Louis XIV had renounced all claims of his family to the throne

of Spain. When Charles II of Spain died, Nov. 1, 1700, Louis ignored his obligations and claimed the throne for his grandson, Philip of Anjou, while the emperor Leopold claimed it for his son, the archduke Charles. The French occupied the fortresses in the Spanish Netherlands in Feb., 1701, and were attacked by the Austrians in N. Italy. William III, foreseeing the conflict, formed a league called the Grand Alliance (*q.v.*), which, having completed its preparations, declared war, May 4, 1702. Marlborough, in command of an army of British and Dutch, advanced into the Spanish Netherlands; a German army crossed the Rhine, and was subsequently defeated at Friedlingen; and the campaign was carried into Italy by Prince Eugene.

In conjunction with the elector of Bavaria, Louis aimed a blow at Vienna, to counter which Marlborough made a remarkable march to the Danube, joined forces with Eugene and defeated the French at Blenheim (*q.v.*), Aug. 2 (O.S.), 1704. The French withdrew across the Rhine, followed by Marlborough, who carried the war into the Moselle valley. In 1705 he returned to Flanders and gained the whole country by his victory at Ramillies (*q.v.*), May 23, 1706. Meanwhile, Eugene had beaten the French in Italy, Great Britain had captured Gibraltar, 1704, and fortune seemed against France. The campaigns of 1707 were more or less failures, and early in 1708 the French seized Ghent and Bruges.

But Marlborough gained another victory at Oudenarde (*q.v.*), July 11, 1708, recaptured the lost cities, and took Lille. Louis then asked for peace, but the Allied terms were too onerous. Tournai was taken, the French Marshal Villars was defeated at Malplaquet (*q.v.*), Sept. 11, 1709, and Mons fell to the British. But Marlborough was recalled and dismissed by the Tories in 1710, and the war dragged on until an armistice between Great Britain and France was signed in June, 1712. Holland, Prussia, and Savoy continued the war until the peace of Utrecht (*q.v.*), April 11, 1713, and the new emperor Charles VI fought on for another year, concluding a peace at Rastatt, ratified in the treaty of Baden (*q.v.*), Sept. 7, 1714.

After the fall of Gibraltar in 1704 the British and Dutch, cooperating with the Archduke Charles, took Barcelona, Oct. 9, 1705, while another force, under Galway, entered Madrid in 1706. But the success was short lived. Madrid was

taken by the French commander, the duke of Berwick, who defeated Galway on the plain of Almanza (*q.v.*), April 25, 1707.

The result of this war was that the Bourbon candidate Philip of Anjou retained the throne, on the condition that no one person should ever wear the crowns of both France and Spain. Austria obtained the Spanish Netherlands, the duchy of Milan, Naples, and Sardinia, which last was later exchanged for Sicily, originally awarded to Savoy. Great Britain secured Newfoundland, Nova Scotia, Hudson Bay, Gibraltar, and Minorca, and important trading rights. Consult *History of the War of Succession in Spain*, Lord Mahon, 2nd ed. 1836; *The War of Succession in Spain*, A. Parnell, 1888.

Spanish Town. A town of Jamaica. It is a rly. junction on the Cobre river, 15 m. by rly. W.N.W. of Kingston. Founded by Diego Columbus in 1525, and originally called Santiago de la Vega, it was the capital of the island until 1871. Pop. 12,007.

Spanner. Implement for turning a nut on a bolt or a screw. It consists of a steel lever, or tube, or separate socket, shaped to conform with the outside of the nut. The lever type may have jaws at one end only, or at both ends so as to serve for two sizes of nut. These are "set" spanners, *i.e.* adapted for a fixed size. In adjustable spanners a loose jaw actuated usually by a screw can be brought up to a fixed jaw so as to accommodate variously sized nuts within its limits of movement. The adjustable spanner has more the nature of a wrench (*q.v.*).

When there is not room to permit the swing of a lever spanner, a tubular type or one of the socket spanners is used. The tubular spanner is either single- or double-ended, the end(s) being shaped to fit snugly on to a nut. A hole diametrically across the tube allows a tommy-bar to be inserted to twist the tool. The socket spanner has a shaped socket to fit the nut, and a polygonal hole on the back surface to take a corresponding rod by which the socket is twisted for unscrewing or screwing the nut. Commonly one end of the bar is straight; the opposite end is bent at right angles for ease of application in awkward positions. The box spanner resembles the tubular type but is formed from solid metal, and has a T-handle, or a hole in which a tommy-bar can be inserted.

A ratchet spanner has the turning member connected to the lever by a ratchet, which can be used for right- or left-handed rotation, or fixed for use like an ordinary set spanner. Air-operated or electrically driven nut-runners are used for jobs where many nuts have to be put on bolts. The spanner unit resembles the socket spanner, and is rotated and given impact by a combined rotation-percussion mechanism in the driving tool.

Spar. In mineralogy, term used for crystallised minerals. The word is usually qualified by a name indicating the mineral, e.g. calc-spar, fluorspar, etc. The word is also used for part of the rigging of a ship. *See Ship.*

Sparassis Crispa. Fine edible fungus of the family Thelephoraceae, growing on the roots of pine

Sparassis Crispa. Edible fungus that grows in pine woods upon the roots of the trees

trees in woods. From a thick, fleshy base the fungus repeatedly branches, the ultimate divisions taking the form of brittle plates more or less twisted, and of a cream or pale brownish tint. The entire mass is ordinarily the size of a man's head, but may be 1½ ft. in diameter. In a raw state it has a nutty flavour.

Sparaxis. Genus of bulbous or tuberous perennials of the family Iridaceae, natives of Africa. They have a few sword-shaped or lance-shaped leaves, and rather large tubular flowers of yellow, white, or purple, variously spotted or mottled. *S. bulbifera* has edible tubers.

Spark. Small shining body of light, usually a small ignited particle shot off from a fire. An electric spark is a disruptive discharge of electricity which takes place between two conductors at different potentials when the electrical resistance of the medium between them breaks down. The length of a spark increases with the

potential difference, and varies with the medium and, for a given voltage, with the form of the conductors. In air at normal pressures between spherical electrodes 2 cm. diam., it requires 8,500 volts to obtain a spark 2 mm. long, and 72,000 volts for a spark 40 mm. long. With point electrodes much smaller voltages are necessary.

Spark Plug. Electrical device for igniting the explosive charge in an internal combustion engine (*q.v.*). There is a gap, one side of which is "earthed" to the engine frame, the other side being insulated from the frame and subjected to a sufficiently high voltage to cause a spark to pass across the gap at the required moment. The voltage required depends upon the width of the gap and the density and temperature of the explosive mixture surrounding the plug. The gap width depends upon speed, compression, and position of plug, but its average is about 0.02 in., requiring a voltage of 4,000 to 5,000 under working conditions.

The plug body, to which the external points of the gap are fixed, is screwed into the cylinder head, making good metallic contact, and fitted internally with a tube of insulating material (usually porcelain or mica) which is secured by a nut and insulates a small metal conducting rod passing down the centre. At its upper end this rod is screwed and fitted with a nut making electrical connexion with an insulated wire from the magneto or induction coil distributor. The insulating bush must withstand high temperatures and

Spark Plug. Diagram explaining construction. *See text*

voltage. When leaded fuels are used the central electrode is often made of tungsten or nickel. *See Magneto; Motor Vehicle.*

Spark Transmitter. Device for obtaining electrical oscillations of radio frequencies by suddenly short-circuiting a charged condenser through a suitable induc-

tance and spark-gap. With the development of the thermionic valve this type of wireless transmitter has almost disappeared.

Sparrow. Genus of Passerine birds, of which the best known is the house sparrow (*Passer domesticus*). This, the familiar small, black-streaked brown finch, has followed man in his advance over the globe so thoroughly that its original country is now uncertain. Hardiness, impudence, cunning, and fecundity have made the sparrow the dominant species of small bird. There are three or four broods in the year.

The bulky and untidy nest is made of whatever materials are handy—hay, straw, roots, rag, string, bits of paper—but always lined with soft feathers. The eggs are white, tinged with blue or green, variously streaked or spotted with brown or purple. Though destructive, the sparrow eats innumerable insects, and is a useful scavenger. The male is distinguished by his black throat and by his coloration, being more ashy than the female.

The tree sparrow (*P. montanus*) is slightly smaller, and has brown plumage, with a white collar around the throat and two white bars on the tail. It occurs locally in England and Scotland, but is rare in Wales and Ireland. It nests in hollow trees, under the thatch of old buildings, and in holes in rocks; and rears two or three broods in the season. *See Accentor.*

Sparrow Force. Guerrilla force operating in Timor, E. Indies, in the Second Great War. After the Japanese occupied the island in 1942 an Australian, Dutch, and native force was formed which harried the enemy. It was supplied from Australia, after establishing radio contact with Darwin when it had been isolated for a year, and continued to harry the Japanese until their general surrender in 1945.

Sparrow Hawk (*Accipiter nisus*). British bird of prey, found in most country districts. The plumage is bluish grey on the upper parts, and reddish white, barred with dark brown, on the under parts. The tail is barred with grey and black, and the beak is blue. The female, 3 ins. longer than the male, has brown upper parts, while the under parts are barred with light and dark grey. This bird is very destructive in game coverts during the breeding season. *See Eggs colour plate; Hawking.*

Sparta. One of the two most renowned cities of ancient Greece, the chief of the Dorian division of

the Hellenic race, known also as Lacedaemon. The town lay in Laconica, the S. division of the Peloponnese, remote from the sea and hard for an enemy to reach. The rule of the Spartans extended over Laconica, and sometimes a good deal farther. The Spartans themselves, who occupied the open town of Lacedaemon, were a small group of Dorian clans forming a military caste which, after the Dorian conquest about the 11th century B.C., established their supremacy over the rest of the tribes in that part of the country, whom they called Perioeci (q.v.).

The Spartan city state was a compromise between monarchy, oligarchy, and democracy. Sparta had two kings, reigning jointly, with limited powers save for the absolute control exercised by one or other of them over armies in the field. Ordinary conduct of administration was in the hands of the aristocratic council; but the actual supreme control, the ultimate authority, was in the hands of the ephors, officers annually elected or chosen by lot from among the free Spartans, the democracy. The joint kingship probably arose from the union of two tribes. The nobles secured an effective predominance through the right of naming the supreme officers of the state.

Bred to be Soldiers

The Spartan system was directed to a single supreme end, that of military efficiency. Spartans were bred to be soldiers, contemptuous of all the amenities of life, no less so of pain and death. They were trained not to eloquence but to curtness of speech; all luxuries were prohibited; courage was their one supreme virtue; the women were bred to become the efficient mothers of soldiers.

The Spartan system was by tradition universally attributed to a law-maker named Lycurgus (q.v.). During the 8th and 7th centuries, the Spartan state was engaged in establishing its supremacy over the greater part of the Peloponnese, in the suppression of Messenia, and in the struggle with Argos, long its rival for the hegemony. Military superiority was at length thoroughly established, and Sparta became the recognized head of all Greek states acting together for military purposes.

But Sparta was sluggish, slow to act, not easily moved by considerations of justice, and still less of generosity. When the Ionian cities of Asia Minor revolted against the domination of Persia, it was Athens, not Sparta, which sent

them aid, 499 B.C. When Darius demanded from the Greek states earth and water, the symbols of submission, Sparta refused as defiantly as Athens, but when in 490 B.C. the great king sent a punitive expedition, the Spartans dallied before sending their troops to aid the Athenians, and it was the Athenians who, single-handed, drove the Persians back into the sea at Marathon. Ten years later, 480, when Xerxes poured his vast armies overland into the Greek peninsula, the Athenians took the seas, and the Spartans with their advance guard held the pass of Thermopylae, where under their

Sparta. Map of the state of Laconica, the territory of the city of Sparta

king Leonidas the famed Three Hundred fought and fell. To Athens, not to Sparta, belongs the glory of the sea-fight at Salamis in the same year; but it was under the leadership of the Spartan king, Pausanias, that the Greek armies won the battle of Plataea (q.v.).

With the prestige won by Athens in the Persian wars begins the rivalry between Athens and Sparta for the leadership of the Hellenic world. Athens made herself supreme on the seas, and supreme in literature and art; but Sparta still sought to be the dominant power. In 431 the definite struggle began. Ten years of contest left the fight drawn, and the war was temporarily suspended; but Athens dissipated her power in a disastrous expedition to Sicily, and in 412 Sparta renewed hostilities. Athens was rent by political dissensions, yet it was not till the Spartan general Lysander realized that Athens could not be crushed until her naval power was broken, and annihilated the Athenian fleet at Aegospotami, 405, that Sparta achieved the decisive victory.

For 25 years Sparta was the dictator of the Hellenic world, but in 379 the city of Thebes, in Boeotia, revolted against her domination. Under the leadership of Epaminondas (q.v.), the Thebans, after a long struggle, not only won their own freedom, but for a time the supremacy of Greece. The Spartan ascendancy was never recovered after the great Theban victory at Leuctra in 371. The Theban ascendancy sank almost as rapidly as it had risen on the death of Epaminondas at Mantinea in 362, and a new power—that of Macedon—was coming upon the stage. The day of the small city states was over when Philip of Macedon won his decisive victory at Chaeronea in 338. Greece passed under the supremacy of Macedon, and Sparta sank almost into insignificance.

Just about a hundred years later she enjoyed a brief revival under her reforming king Cleomenes, but with his fall in 221 she sank again; nor did she play at all a glorious part in the unsuccessful efforts of Macedon and the Grecian states to stay the conquering progress of Rome in the first half of the 2nd century. Nevertheless, incorporation of Greece in the Roman prov. of Macedonia was not formally completed until 146 B.C. (See Greece; consult Histories of Greece, A. Holm, Eng. trans. 1894-98; G. Grote, new ed. 1907; J. B. Bury, new ed. 1908.)

Sparta today is the capital of the Greek dept. of Laconia. Pop. 5,800.

Spartacists. Group of extreme Socialists (Ger. *Spartakusbewegung*) which came into being in Germany, particularly Prussia, at the end of the First Great War. Influenced by the Bolshevik victories in Russia in 1917, they derived their name from Spartacus (v.i.), leader in the Servile War against Rome, 73-71 B.C. The leaders in their attempt to set up a proletarian dictatorship were Karl Liebknecht and Rosa Luxemburg. After both had met their deaths in 1919 through the police of Noske, right-wing Socialist minister of the interior, the movement lost drive and importance, but it may be regarded as the forerunner of the German Communist party.

Spartacus (d. 71 B.C.). Thracian soldier who commanded the insurgents in the third Servile War of Rome. Originally a shepherd, he was taken prisoner by the Romans and trained in the gladiators' school at Capua, whence in 73 B.C. he escaped with 70 others to the

crater of Vesuvius. Having scattered a blocking force, he gathered an army of runaway gladiators and other slaves, estimated at 100,000 men, and devastated Italy from end to end, displaying remarkable military skill and strenuously endeavouring to restrain the excesses of his men. In 71 he was defeated and slain by Marcus Licinius Crassus. *See* Servile Wars.

Sparteine. Alkaloid obtained by extracting broom-tops (*Cytisus scoparius*) with acidulated water and distilling the extract with caustic alkali. Sparteine is an oily liquid with a bitter taste. Its salts are used in medicine in the treatment of heart disease.

Spartel. Cape of Africa. On the N.W. coast of Morocco, in the international zone, it is at the entrance to the Strait of Gibraltar. Its height is 1,020 ft.

Spasm. Involuntary contraction of a muscle or group of muscles. A short, repeated contraction or twitching of a muscle is known as a clonic spasm, a continuous contraction as a tonic spasm. Spasms may be due to hysteria, reflex irritation of a nerve, or various diseases of the nervous system. A mild form of hysterical spasm, in which a group of muscles are contracted at intervals, causing, for example, lifting of the eyebrow or pulling down of an angle of the jaw, is known as habit-spasm. A severer form is termed a tic.

Spaté (Dutch *spuiten*, spout). Term applied to a mountain torrent in flood. When heavy rains or the sudden melting of snow brings freshets down the rocky bed, the river is in spaté.

Spathe (Gr. *spathē*, broad blade). In botany, the sheathing bract enclosing one or several flowers. A common example is seen in the narcissus. A fleshy spike of flowers covered by a spathe is called a spadix. The object of the spathe is to protect the young flowers, and after the latter expand it usually withers or falls off. *See* Spadix.

Spathic Iron Ore. The technical name for this substance is siderite (*q.v.*).

Speaker. Presiding officer of the British house of commons. The first person to receive the title was Sir Thomas Hungerford in 1377. He and his successors were called speakers because it was their duty to voice the wishes of members of the house to the king. The speaker is elected by the members, and receives a salary of £5,000 a year

and a residence. In order of precedence he ranks immediately below the lord president of the council and above the lord privy seal. He represents the commons on ceremonial and other occasions, and is made a viscount and pensioned on retirement. He takes no part in party politics during his term of office. Col. D. Clifton Brown, M.P. for Hexham, became speaker in 1943. The lord chancellor is the speaker of the house of lords. Some legislatures modelled on the English one call their president the Speaker, *e.g.* the house of representatives in the U.S.A. and the two houses of the Canadian legislature. *See* Committee; Parliament; Ways and means.

Spear (A.S. *spere*, perhaps cognate with *spar*). Offensive weapon, consisting of a sharply pointed

Europe. It is widely cultivated for culinary purposes. It has creeping, underground stolons, erect aerial stems, and opposite, oval-lance-shaped leaves, with pungent odour. The stems end in spikes of whorled purplish flowers.

Sir Edward Spears, British soldier

Spears, Sir Edward Louis (b. 1886). British soldier and politician. Born Aug. 7, 1886, and educated privately, he entered the Kildare militia in 1903, passing to the 8th Hussars 1906, and during the First Great War, in which he was four times wounded and won many British and foreign decorations,

Spear. 1. Barbed weapon used by Fiji Islanders. 2. Broad-headed Sudanese spear. 3. English hunting spear of the 16th century

shaft, used in war and the chase. It may be thrust or hurled. Specialised forms are the pike, lance, javelin, dart, arrow, and bayonet. The shaft, of varying length, is usually of wood, and the pointed head of metal. A bone point probably succeeded the charred end of a stick, and in the Palaeolithic age flint spearheads already occur. In the late Bronze age spearheads, with sockets or tangs, and sometimes barbs, were cast in moulds. The spear was the chief weapon in the Homeric age. The later Greeks and Romans used spears hurled with the aid of a thong attached to the middle of the shaft.

Many types of spear, headed with metal, bone, chipped flint, and other kinds of stone, are used at the present day by backward races, for fighting, hunting, and fishing, the tips being sometimes poisoned. Among civilized races the spear, apart from forms like the lance, is used chiefly for pig-sticking and spearing eels. *See* Anglo-Saxon Antiquities; Arms; Lance; Pike.

Spearmint. Leaves and flower whorls

Spearmint (*Mentha spicata*). Perennial herb of the family Labiatae, native of

rose to be brig.-gen. and head of the British military mission to Paris, 1917-20. He was National Liberal M.P. for Loughborough, 1922-24, and Conservative M.P. for Carlisle, 1931-45. In 1940 he was made a major-general and was British liaison officer to the French prime minister. He headed a mission to Syria and Lebanon in 1941, and from the next year, when he was knighted, until 1944 he was minister there. Spears married in 1918 the novelist Mary Borden (*q.v.*). His books include *Liaison*, 1930; *Prelude to Victory*, 1939.

Spearwort (*Ranunculus lingua*). Perennial herb of the family Ranunculaceae, native of Europe

and temperate Asia. It is found chiefly in marshes and ditches. The hollow stem is about 3 ft. high, with large, stalkless, lance-shaped leaves that clasp the stem at their base. The fine, golden-yellow flowers are an inch and a half across. The lesser spearwort (*R. flammula*) is similar, but is

Spearwort. Flower and blossoms of *Ranunculus flammula*

smaller in all its parts. The lower leaves are stalked and oval, the upper stalkless and lance-shaped.

Special Air Service. Unit of the British army. Formed in 1941, it consisted of selected parachute troops, trained on commando lines, expert in navigation, and skilled in all types of weapons. They operated in small formations, rarely more than 12 men, and were dropped behind enemy lines or in occupied territory to sabotage selected targets. The unit first went into action in Nov., 1941, when it unsuccessfully attempted to destroy a German aerodrome in France. The next month a number were dropped near Benghazi and destroyed a German airfield and 100 aircraft. Until 1943 the Special Air Service was operating behind the enemy lines in N. Africa. The regiment subsequently played a notable part in the invasions of Sicily, Italy, and Europe, creating havoc behind the enemy lines by disrupting communications. The disorganization of German resistance in depth in France after Gen. Patton's breakthrough in Normandy was largely due to the S.A.S., working in conjunction with the Maquis. After the Second Great War, only a cadre of Special Air Service personnel was retained. In 1947, the Artists' Rifles, a Territorial unit, was converted into a Special Air Service regiment.

Special Area. British district with a high level of unemployment. Formerly known as a distressed or Depressed Area (*q.v.*), after the Second Great War it was called a development area.

Special Case. In English law, a statement of facts to be laid before the judge of the high court, so as to obtain a decision upon a point of law. In any action the parties may agree on a joint statement of the facts, and ask the court to say who, in law, is in the right. An arbitrator may be asked to state his findings in the form of a special case, in which event he must say what are the facts as he finds them, and then one of the parties moves the court for judgment on these facts. Justices of the peace may state a case for the opinion of the high court. They must state a case if asked to do so.

Special Constabularies. In the U.K., auxiliary bodies drawn from the citizenry to assist the regular police in times of special danger or emergency. Under the Special Constables Act, 1831, any able-bodied person refusing to serve is liable to a penalty. Special

constables were sworn at the time of the Reform riots, 1831, and during the Chartist demonstrations, 1848, when one was the future Napoleon III, then living in London. They were called out in the general strike, 1926. In both Great Wars special constables helped in routine duties and air raids; in the First they were enrolled on a part-time basis, but in the Second some worked full time. *See* Constable; Police.

Special Licence. A form of marriage licence granted on certain conditions, and in exceptional circumstances. Special licences are granted only by the archbishop of Canterbury, and enable the holder to be married at any time or place without previous residence in the district. The applicant for such a licence must produce satisfactory reasons why it should be granted. Special licences are issued by the Faculty Office, 1, The Sanctuary, Westminster, S.W.1, the fees amounting to £25. *See* Marriage Law.

Special School. Institution for children with some mental or physical disability. *See* School, p. 7365.

Special Service Troops. These are more familiarly known as commando units. *See* Commando.

Specialty. In English law, a contract made under the seal of the parties to it, *i.e.* a deed. An action on a specialty may be brought at any time within 12 years from the date when the cause of action accrued. The period for other contracts is 6 years. No consideration is required for a contract by specialty.

Species (Lat., appearance, sort, kind). In logic, a group subordinate to a genus, consisting of individuals with certain attributes in common. In biological classification, a species is a group intermediate between a genus and a variety. The division of living things into kinds or sorts sufficiently discontinuous and distinct to make it possible to place an individual in the great majority of cases, unerringly among its fellows is a fact of nature. It is usually taken for granted, but it is by no means clear how this fact of nature came into being. There seems to be no *a priori* reason to expect that when metabolism began, that is to say when certain proteins occurred and behaved as their structure and environment required, they should become progressively differentiated from one another; but they did. The process of differentiation by a series of steps taken through time

amounts to a kind of logical division of living material based fundamentally on the occurrence or non-occurrence of a change of structure in a gene (mutation, *q.v.*). Further, once a mutation has occurred, then, if the mutant gene is viable and coexists with the unchanged original form, not only do two alternative forms, two kinds, of living things exist where there was one before, but there is an increased chance of further variation, because these two forms, being different, will be affected differently by random incidents, such as the arrival of radiations, and will be differently liable to later physical and chemical change. This is a consideration of great importance. It means that in a very special way the differentiation of living things is autocatalytic.

For a mutant form to survive it must continue to metabolise—that is, to use its environment for replication. Without an environment to be so used the notion of living has no meaning. For this reason a second, externally applied, force imposes linearity on the process of differentiation: not only are changes made possible or impossible by previous changes in molecular structure, but forms are made viable or inviable by the facts of the environment. Since, in an extreme case, the environments of land, water, and air are discontinuous, a discontinuity is imposed in this secondary way on the lines of development and differentiation followed by rabbits, trout, and sparrows. In those forms where no fusion of individuals occurs in any kind of sexual process, kinds or species will be differentiated as a result of the considerations described. It is often very hard to distinguish such kinds, and in pathogenic forms on which most work has been done it is often necessary to distinguish kinds or "strains" of organisms by their pathological effects.

A very great complication is introduced into the whole concept of the species by the fact of sexual fusion. The moment two individuals fuse the whole validity and integrity of the groups defined by the processes outlined is imperilled. The dichotomous logical division implemented by mutation fails: the middle is no longer excluded because the heterozygous individual has both changed and unchanged genes. The group set up on the simple dichotomous system described becomes immediately explosive.

The only group which can maintain its validity in these circumstances is one within which the fusion of individual gene-sets is rigidly contained. The functional species in nature is, therefore, the breeding group, the group within which genes circulate. The discontinuity, in nature, is between such groups, which are the natural species; these are the groups upon which natural selection works, often giving them specific characters, not, however, always easily recognizable.

Specific Gravity. The ratio between the weights of equal volumes of any substance and of some other substance that has been chosen as a standard. For gases the standard chosen is hydrogen or air; for liquids and solids, water. The ratio is usually determined at some standard pressure and temperature. Water is at its maximum density at 4° C., and specific gravities of other liquids and of solids are usually defined at that temperature.

The specific gravity of solids and liquids is determined generally by methods based on the law of Archimedes that a solid, floating or immersed in a liquid, loses weight equal to that of the liquid it displaces. If, therefore, the solid is totally immersed, the loss of weight is equal to the weight of a volume of liquid the same volume as that of the solid. From this the specific gravity of the solid may at once be obtained, since the ratio of the weight of the solid to its loss of weight is the same as the ratio of the specific gravity of the solid to that of the liquid.

Special balances are used to enable the solid to be accurately weighed in air and in water. The specific gravity bottle is a glass flask fitted with a stopper containing a fine hole. By this means the bottle may be completely filled. It is weighed empty and full of water, and afterwards full of a liquid of unknown specific gravity. From these weightings the specific gravity of the liquid may be determined.

Hydrometers (*g.v.*) will also determine the specific gravities of liquids. A third method of obtaining the relative densities of two liquids is by immersing an inverted U-tube in the liquids, one leg in each liquid. The bend of the tube contains an opening, leading to a short side tube with rubber tubing and clip, by which the liquids may be drawn up by suction. The heights to which they rise are inversely proportional to their densities. For non-mixing

liquids two equal volumes may be poured into an ordinary U-tube; the lengths of the two columns enable the relative densities to be calculated.

The specific gravity of a gas is generally found by making use of the law that the rate of effusion of a gas varies inversely as the square root of its density, for a given difference of pressure on each side of the opening through which effusion is taking place.

Specific Heat. Quantity of heat necessary to raise the temperature of 1 gram of a substance through 1° C. at any given temperature. If 100 grams of water at 100° C. is mixed with 100 grams at 0° C. the temperature of the mixture is approximately 50° C. But if 100 grams of copper at 100° C. is placed in 100 grams of water at 0° C. the resulting temperature of the water and copper is about 9.1° C. The heat given out by the copper in cooling through 90.9° C. has heated an equal mass of water through 9.1° C. The copper requires much less heat to raise its temperature than does the water; in fact, its specific heat is only about one eleventh that of water.

The amount of heat necessary to raise the temperature of a substance through 1° varies at different temperatures, and so the degree of temperature at which the increase by one degree is made should be specified. If the specific heat of water at a temperature of 15° C. is taken as unity, then the specific heat of water at 5° C. is 1.0041. That is, it takes more heat to raise a gram of water from 5° to 6° than it does from 15° to 16°. Specific heat of metals falls rapidly as absolute zero is approached.

Strictly speaking, the term specific heat should refer to the ratio between the heat capacity of a substance and that of water. Since, however, the unit of heat, the calorie, is itself defined in terms of the heat capacity of water, this ratio has the same numerical value as the heat capacity per gram, and specific heat is now customarily used both for the ratio and for the absolute value in cal gm⁻¹ deg. ⁻¹.

The usual method of determining the specific heat of a solid is to heat a mass of the solid to a known temperature, and then immerse it in a vessel containing a known mass of water. The temperature of the vessel, known as the calorimeter, is noted at the beginning and end of the experiment, and

proper allowances are made for the escape of heat by radiation, etc.

The specific heats of gases are more difficult to determine than those of liquids and solids, not only on account of the comparative bulk of the gases, but because they have different specific heats according to whether they are allowed to expand or not when heated. The heated gas is passed through a metal worm heated to a known temperature, and then through a spiral immersed in water. The rise in temperature of the latter enables the specific heat of the gas to be calculated at a constant pressure. If the volume is kept constant, a globe containing a volume of the gas at a known temperature is immersed in a steam calorimeter, and a certain quantity of steam is condensed in raising the temperature of the gas and the globe. From this the specific heat is reckoned.

In such experiments the thermal capacity of the container is a large fraction of the total thermal capacity of the system, and careful allowance has to be made for it.

The specific heat of most substances is different in the three states, gas, liquid, and solid. Thus the specific heat of ice is 0.5, of water 1, of steam 0.477.

Specific Inductive Capacity. The ratio of the permittivity of a substance to that of air (or more properly of a vacuum). The capacity of an electric condenser is increased by substituting some other dielectric for air between the plates. The permittivity, or dielectric constant, is a measure of the power of any given material to increase the electric influence between the plates of a condenser.

Spectaclemakers' Company. London city livery company. It received a charter in 1629, con-

Spectaclemakers' Company arms

trolled the spectacle trade until the end of the 18th century, and was granted a livery in 1809. In 1898 it inaugurated a scheme for granting diplomas to opticians. The offices are at Apothecaries Hall, Black Friars Lane, London, E.C.4.

Spectacles (Lat. *spectaculum*, show). Device for aiding subnormal eyesight and relieving headaches due to eyestrain. It consists of lenses made from high quality glass or plastic material with high light-transmitting property. These are mechanically supported before the eyes by

frames with supports over the ears, made of tortoise-shell or plastic. Metal frames are less commonly used than formerly, but rimless spectacles are regaining the popularity they lost to the "horn-rimmed" type which appeared after the First Great War.

The invention of spectacles is probably due to the Chinese, and there are references by Latin writers to an eyeglass of beryl worn by Nero. Alessandro de Spina, a Florentine monk, and Roger Bacon are both credited with their invention in Europe. Primitive spectacles are depicted in paintings of c. 1350, but it was not until the late 16th century that manufacture became general.

Lenses are divided into two main classes, spherical and cylindrical, each subdivided into concave and convex and their combinations. Concave lenses are used for the correction of myopia or short sight; convex for hypermetropia or long sight. Cylindrical lenses correct astigmatism. Prismatic lenses are suitable for double vision, and for the correction of strabismus or squint in conjunction with motor exercises of the external muscles of the eyeball, this science being known as orthoptics. Lenses in various tints can be worn in strong sunlight, and by industrial workers where heat and light absorption is a necessity. Crookes was largely responsible for their introduction. Bifocal lenses set right both distant and near vision in one pair of spectacles, and to Benjamin Franklin is given the credit for their invention.

For the correction of defective vision there have been evolved contact lenses which fit on the eyeball itself. They consist of a hollow shell of glass or plastic made to fit the anterior surface of the eyeball, the power of the lens being confined to a small central portion. Placed inside the eyelids they are almost invisible. *See Eye; Optical Glass; Sight Testing.*

Spectator, THE. Periodical essays begun by Joseph Addison, March 1, 1711, in succession to The Tatler. They were issued daily until Dec. 6, 1712, and then revived June 28, 1714, and issued thrice weekly until Dec. 20 the same year. In descriptive, critical, anecdotal, whimsical, and humorous fashion the essays taught sound social lessons of tolerance, moderation, and good sense. Of the 635 issues of the periodical, Addison wrote 274, signed by one

of the initial letters C. L. I. O., and Sir Richard Steele 240; the rest being by various minor writers; but whoever wrote the essay always did so as Mr. Spectator. *See Addison, J.; Coverley; Steele, Sir R.; Tatler, The.*

Spectator, THE. London weekly review. Taking the title of the periodical associated with the names of Addison and Steele, it was founded July 5, 1828. Its features include a commentary on the week's news, political and social articles, literary criticism, and correspondence. Notable always for its independence, it has exercised more influence than most London journals. Its editors have included R. S. Rintoul, 1828-58; R. H. Hutton, 1861-97; J. St. Loe Strachey, 1897-1927; and from 1932 H. Wilson Harris. For a time Sir Evelyn Wrench was in control, and he remains a substantial shareholder.

Spectrographic Analysis.

Method of analysis of materials which has developed largely during the 20th century into an important branch of science. Almost any material can be subjected to analysis with interesting results, for the presence of elements down to minute traces can be detected and often accurate quantitative estimates made. After Ångström in 1870 had made some extremely accurate measurements of wavelengths, Lockyer and Roberts suggested the possibilities of quantitative analysis with the spectrograph. Little further action was taken until the 1900s, when Hartley and de Gramont introduced *raies ultimes*, which formed a basis for the science. In 1909 Twyman designed a medium quartz spectrograph with fixed adjustment, and a few years later the large adjustable instrument. The science is used in the majority of industrial and research laboratories. But as no quantitative analysis can be made without standards which have first been accurately analysed by normal chemical methods, spectrographic analysis must be regarded not as a substitute for but as an aid to chemical analysis.

The method depends on several fundamental physical factors. Although wave mechanics have shown that it is not wholly true, it is convenient to use Bohr's simple conception of the atom as a nucleus with a series of electrons, carrying negative charges and revolving round the nucleus at high speeds in certain orbits. Each element holds a number of

characteristic electrons at various energy levels. The electrons prefer to move in orbits of minimum energy, known as stationary states. Emission of light corresponds to a transition from a higher to a lower energy level, and absorption of light to the reverse transition, the transitions being brought about by the fall of electrons, which have previously been displaced into higher energy levels by some input of energy or exciting force. This energy may be supplied by a flame, electric arc or spark, or a discharge tube, and, when the electron returns to its lower energy level, it causes the emission of energy which may be measured in terms of volts, calories, or frequency of light.

Atomic physics has shown that the emission or absorption of light can take place only along certain definable lines; hence light of characteristic wavelengths is emitted or absorbed. The prism or diffraction grating of the spectroscope (or spectrograph, a spectroscope with a camera attached) disperses these wavelengths to produce spectra, which, because of the inherent differences in energy levels in the various atoms or molecules, are characteristic of those atoms or molecules. Any element, owing to the distribution of energy inside the atom, can liberate or absorb energy only in certain characteristic quanta. If it is known that a certain element and no other emits light of certain wavelengths, then, if lines of those wavelengths are located, that element must be present in the source of light. Further, with some reservations, the amount of energy released at those wavelengths, i.e. the intensity of light emitted, is proportional to the amount of that element present.

Method of Analysis

So the system of analysis in emission spectroscopy is to burn the sample, which need be only a few milligrams in weight, in a flame, electric arc, or spark. The light from this source is passed through a spectrograph and a photograph or spectrogram is taken. By studying the positions of the spectrum lines it is possible to identify all the elements present in the sample. *Raies ultimes* or persistent lines will appear even if the element is present in amounts which would not be detected chemically or by any other means at our disposal. If the conditions of emission and of taking the spectrogram are

rigidly standardised, the intensity of blackening of certain lines will be proportional to the amounts of the elements present. If light is then passed through the developed plate and thence on to a photo-electric cell, the current given by the cell will be a measure of the density of blackening of the photographic plate, which is proportional to the intensity of the light causing this line and so to the amount of the element present. Errors due to slight variations in conditions can to some extent be compensated by the use of an internal standard.

Applications of the method range from the analysis of ores, rocks, minerals, clays, metals, and alloys, to forensic chemistry, crime detection, testing the purity of chemicals and other materials, and determination of the composition of stars, planets, and the sun. Methods have been developed to avoid taking a spectrogram by introducing the photo-electric cells into the spectrograph where the camera should be, and so getting a direct reading of the intensity of light emitted. With such an instrument it is possible to determine quantitatively seven elements in *e.g.* an aluminium alloy in 3-4 mins.

This emission spectroscopy has been augmented by the analysis of absorption spectra, where the reverse electron transitions are used and the absorption of light at certain wavelengths is measured. Much of this work is carried out in the infra-red region of the spectrum and on solutions or oils. Chiefly applied to organic and inorganic chemical compounds, it is of interest to biochemists, medical research workers, dye chemists, and others. See *Astronomy; Atom; Electronics; Photo-cell; Physics; Spectroscopy. Consult Chemical Spectroscopy, W. R. Brode, 2nd ed., 1948.*

F. D. L. Noakes

Spectroheliograph. Instrument for photographing the prominences of the sun. A development of the spectroscope, it was invented by G. E. Hale and M. Deslandres, and enables different layers of the sun's atmosphere to be studied in mono-chromatic light, that is to say, light of one kind or, more scientifically, of one wavelength.

The ordinary spectrum of the sun is spread out from a slit through which its light passes. In the spectroheliograph a second slit is used, so that only a very narrow portion of the spectrum is able to reach the photographic plate. This secondary slit is so adjusted that it can be made to isolate any desired spectrum line, *e.g.* the K line of calcium or the red line of hydrogen, and allow the light passing through this line only to fall on the photographic plate. By allowing the sun's image to travel across the first slit, while the plate travels behind the second slit, an image of the sun is built up strip by strip, as photographed by light proceeding from the calcium in the sun.

Adaptation of the spectroheliograph to the ciné-camera was accomplished by McMath and Hulbert of the university of Michigan, the device being known as a spectroheliokinematograph.

Spectrohelioscope. Instrument for viewing the sun in light of one particular wavelength. Invented by G. E. Hale in 1926, it is the visual counterpart of the spectroheliograph (*v.s.*), the eye taking the place of the photographic plate. The primary image of the sun is kept still, as is also the observer's eye, but the two slits are moved back and forth in conjunction so rapidly that by the phenomenon known as persistence of vision the observer sees a picture of the sun in the particular wavelength selected. Sev-

tion on the earth have been thereby discovered.

Spectroscope (Lat. *spectrum*, something seen). Instrument by which light is resolved into vibrations of different frequencies, and can thus be examined and its properties defined. It generally includes a slit and a collimator to admit the light in a parallel beam, and a viewing telescope. The Littrow type combines collimator and telescope, making the beam pass twice through the same lens. With a camera replacing the eyepiece, the instrument becomes a spectrograph, and when equipped with measuring scales and circles, a spectrometer.

The actual analysis is effected in refracting spectroscopes by one or more prisms of glass, or other refracting medium, which, by causing rays of shorter wavelength to deviate more than longer ones, splits up the beam into a rainbow spectrum with the red rays nearest the thin edge of the prism. As the dispersion increases with diminishing wavelength, the violet end is spread out more than the red, and the dispersion is called irrational. Small direct-vision instruments are made with an odd number of prisms in one tube, the even numbers reversed and of denser glass, so that for some mean ray the deviations cancel each other, the instrument being used pointing directly towards the light.

For some astronomical purposes the collimator is unnecessary and the prism can be fixed outside the object glass of a telescope (objective prism). For very refined measurements the resolving power of prisms is insufficient and a diffraction grating is used. Fraunhofer first tried an actual grating of fine silver wire, and afterwards an optical grating of parallel lines ruled

Spectroscopy. Spectra of, from top, the sun, nebulae, hydrogen, and coal gas. A-H, Fraunhofer's sign-posts; H_α-H_ε, bright hydrogen lines; K, calcium line. Left, common form of spectroscope. Top, ray of light split up by prism P into rays of heat, Red, Orange, Yellow, Green, Blue, Indigo, and Violet. See text

by a diamond on plate glass. Later, silvered glass was used for reflection instead of transmission, and then speculum metal replaced the glass.

Diffraction spectra are formed in sets, first, second, third order, etc., on each side of the directly reflected rays, with the violet end nearest the central undisturbed image. An idea of them may be obtained by looking at the sun through a feather. Ruled gratings being expensive, cheap replicas, called Thorp gratings, are made by moulding melted celluloid on a ruled grating. Rowland's concave grating acts as its own condenser and focusing lens, thus avoiding the loss of light due to absorption. It yields a perfectly normal spectrum when used in certain positions.

Resolving power is the ratio of the wavelength to the smallest difference of wavelength actually separated by the instrument. With very narrow slit it nearly equals the number of lines in the whole grating multiplied by the order of spectrum considered. Michelson produced a grating with resolving power 300,000, and 1,000,000 is not considered impossible. He also invented a new form of optical grating called an échelon, glass plates of uniform thickness being arranged in steps. The highest resolving power is reached by interferometers, especially Michelson's. In these the analysis is produced by passing the ray between parallel plates of glass, one or both only partially silvered, the phase of emergent rays varying with the number of internal reflections. Consult *The Spectroscope and its Work*, A. F. Newall, 1910; *Experimental Spectroscopy*, R. A. Sawyer, 1945; *Telescopes and Accessories*, G. Z. Dimitroff and J. G. Baker, 1945.

Spectroscopic Binaries. A class of double or binary stars the components of which cannot be separated by the telescope, but which are revealed by periodic displacements in the lines of their spectra. These displacements are due to the relative motion of source and observer in the line of sight. Among the more notable spectroscopic binaries are Capella; Algol; Mizar, which is one of the stars of the Great Bear; Spica; and Beta Lyrae, of which the two components are nearly in contact. See *Doppler's Principle*.

Spectroscopy. Science which deals with the methods of production of the spectra from various sources of light, and also with their study. In 1672 Newton com-

municated to the Royal Society his famous theory concerning the solar spectrum, and in 1815 Fraunhofer discovered the dark lines in it which bear his name, but spectroscopy as a practical science really began with Kirchhoff's interpretation of the Fraunhofer lines in 1859. He suggested that the cooler gases and metallic vapours surrounding the incandescent body of the sun absorbed the lines which they themselves emit when incandescent.

Many known elements were soon proved to be represented, and incidentally several new ones were discovered on the earth, the first few of these being caesium, rubidium, thallium, and indium. The brighter stars showed similar spectra, some including lines attributed to helium, not then known to exist on earth, but since identified in cleveite and elsewhere. Other lines in the solar spectrum, intensified when the sun is low, are due to the atmosphere and are called telluric lines. Of Fraunhofer's sign-posts (A to H) the first two, A and B, are telluric, due to oxygen in the atmosphere; the rest are solar—C and F hydrogen, double D sodium, E and G iron, and H calcium. The spectrum of a light source is an emission spectrum, but media interposed in the path of the light superpose what is called an absorption spectrum by barring the passage of selected rays.

Since most organic substances possess selective absorption spectra in the infra-red (*q.v.*), infra-red spectroscopy is highly important in applied science.

The unit of wavelength (Ångström) is the ten millionth part of a millimetre, formerly called a tenth metre (1 m.)/(10¹⁰).

The International Ångström is defined by assigning the value of 6438.4696 Å to the wavelength of the red line of cadmium in specified conditions. An alternative is the green line (5461 Å) of isotopic mercury 128, produced by neutron irradiation of gold.

The simplest method of determining wavelengths with a prism spectroscope is to photograph a comparison spectrum, usually of iron, on the same plate and deduce wavelengths by interpolation. Flame spectra are the best for the alkaline group, the Bunsen flame being quite hot enough to volatilise them, and the oxyhydrogen blowpipe will suffice for the currency metals, gold, silver, and copper. But more refractory substances require the high tempera-

ture of the electric arc; the element under investigation being introduced either into the arc itself or into a hollow cone at the point of the positive carbon. An even more energetic action is obtained in spark spectra, the spark from an induction coil being passed between poles of the substance to be analysed, or between a platinum pole and a chemical solution of the substance. Some lines are sharp and some diffused at one or both edges. Bands, due to molecular compounds, are sets of lines crowding closer and closer towards one edge.

Zeeman discovered that rays from a light source placed in a magnetic field appeared widened, and with higher dispersion this widening proved to be a resolution into separately polarised rays, a doublet when viewed along the lines of force and a triplet when viewed at right angles to them. Sometimes the resolution goes farther still, one of the green lines of mercury being resolved into no fewer than nine lines.

Between the wavelengths of sets of lines belonging to the same element numerical relations have been found. Balmer's law for the hydrogen series was the first announced, but it is only a particular case of more general formulae adopted by different investigators. From these has been evolved the current theory which regards the atom as a nucleus with a definite number of associated electrons.

The interferometer is now adopted by the International Astronomical Union as the instrument for absolute wavelength determination, and the arc-spectra of cadmium and the rare gases are used as standards of wavelength.

Doppler's principle (*q.v.*) applied to light requires such high velocity of motion between observer and light source to make any appreciable difference to the enormous velocity of light that its only practical application is in astronomy. Applied to determine the rotation of the sun, it showed lines from the E. limb displaced towards the violet (indicating approach), and from the W. limb towards the red (indicating recession), as compared with the telluric lines which are, of course, unaltered by the sun's rotation, and can be readily identified in this way. The uprush of gas in sunspots is shown by the Doppler effect to be very marked. See *Dispersion*; *Light*; *Nebula*; *Prism*; *Star*. Consult *Spectro-*

scopy, E. C. C. Baly, 3rd ed. 1927; *Experimental Spectroscopy*, R. A. Sawyer, 1945.

Spectrum. Coloured bands formed by dispersion when a ray of light from any source is passed through a prism. Spectra are also formed by means of diffraction gratings. The visible portion of the spectrum varies from red, through orange, yellow, green, and blue to violet, but the spectrum is continued beyond the red and violet. The spectra of the sun, stars, etc., are crossed by dark lines, characteristic of the chemical elements. These have enabled the compositions of the stars, etc., to be stated. *See Spectroscopy.*

Specularite or **SPECULAR IRON.** Variety of haematite (*q.v.*), occurring as black rhombohedral crystals with a fine metallic lustre.

Speculation (Lat. *specere*, to look). Literally, a mental view, a theory, a statement of opinion that cannot be proved, *e.g.* one concerning life after death. The word has come to be used specially for a transaction not in the ordinary course of business, which has been entered into because on a mental view of the circumstances it seems to offer a chance of special profit through the movement of prices. Purchases in the ordinary way of business are not speculations; nor are ordinary investments, *i.e.* purchases undertaken primarily as a source of income. A speculation without adequate knowledge of the factors determining the outcome is a gamble.

Speculum Metal. Alloy of two to two and a half parts of copper and one part of tin. The alloy usually also contains a trace of arsenic. It is a hard, white, brittle metal, capable of taking an extremely high polish, for which reason it was once used in making mirrors for reflecting telescopes. It has been superseded to some extent by silvered or aluminised glass. The reflecting telescopes of Lord Rosse were made with speculum metal.

Spee, MAXIMILIAN, COUNT VON (1861-1914). German sailor. Born at Copenhagen, he had a distinguished career in the German navy, which he helped to create. In 1914 he was in command of the Far Eastern squadron, and on the outbreak of the First Great War escaped from China waters. On Nov. 1 he defeated Craddock's squadron at Coronel (*q.v.*). Spee behaved with modesty and chivalry after this success, until on Dec. 8 he was decisively beaten

by Sturdee at the battle of the Falkland Islands, he himself going down with his flagship, *Scharnhorst*. His name was given to the German battleship Admiral Graf Spee (*q.v.*). *See Falkland Islands. Pron. Shpay.*

Speech. Faculty of uttering articulate sounds with the mouth for the purpose of communication, which distinguishes man from the lower animals. The sound of the voice is produced by a current of air passing through the air passages from the lungs, the cavities of the pharynx, mouth, and nose acting as resonators or sounding boxes. Fine movements of the tongue are essential for the production of speech; the formation of the jaw in some prehistoric men suggests that they did not possess full power of articulation. The co-ordination of the various movements necessary to produce articulate speech is governed by a special speech centre in the brain.

Defects in speech may be due to partial blocking of the air passages by catarrh, adenoids, etc., or to paralysis of the nerves supplying the muscles of speech. Hysteria may lead to loss of voice. Stammering (*q.v.*) is another defect.

Injuries to the speech centre in the brain cause loss of articulation or blurring of words. Sometimes there is a defect in the association of things and their names, a chair, for example, being spoken of as a house. This condition is spoken of as aphasia (*q.v.*), the cause most frequently being haemorrhage in the brain or apoplexy. *See Dumbness; Language; Larynx; Pharynx; Phonetics; Pronunciation; Voice.*

Speech House. Public building in the Forest of Dean, Glos. Built about 1680 as the verderers' court for the business connected with the forest, then as now crown property, it stands in the centre of the forest on Speech House Hill, a height 572 ft. above the sea. The building has become an hotel, but the verderers' court still meets there. *See Dean, Forest of.*

Speed. Rate of motion. Speed varies from the imperceptible movement of geological change to the velocity of light, and is usually expressed as distance travelled during unit time. The fastest time for a man walking is one mile in 6 min. 21.2 secs., and for running 100 yards in 9.3 secs., *i.e.* approximately 21 m.p.h. The longer the distance walked or run the lower the average speed; over a distance of a mile, a man's maximum running speed averages 14.9 m.p.h.

The fastest four-legged animal is claimed to be the cheetah, but it has never been officially or scientifically timed. The fastest timed animal is the greyhound, with a max. speed of over 39 m.p.h. A racehorse has maximum speed of 38.5 m.p.h., but only over a short distance; a fox can run at 26 m.p.h. The ostrich is the fastest animal on land; it can run at over 60 m.p.h. Of flying birds, the Arctic blue-throat has a speed of 180 m.p.h., the eagle 140 m.p.h., and the swift 100 m.p.h. The fastest insect is a small S. American fly, *Cephenemyia*, which is half an inch long and travels at over 800 m.p.h.

Mechanical devices enable man to increase his speed to many times that of the swiftest animal. A bicycle has been ridden $\frac{1}{2}$ m. in 24.8 secs. The official maximum speeds in 1950 were: aeroplane, 670.98 m.p.h., set up at Muroc, California, Sept. 15, 1948; motor road vehicle, 393.875 m.p.h., by John Cobb on Utah Flats (U.S.A.), Sept. 16, 1947; fastest speed on water, 160.32 m.p.h., by S. Sayers, on Lake Washington (U.S.A.), June 26, 1950; greatest railway speed, 125 m.p.h. attained by the L.N.E.R. engine Mallard, on the Grantham-Peterborough run, July 3, 1938. The fastest sustained speed by a train on regular service is 86.2 m.p.h. averaged by the Burlington rly. Twin Zephyrs diesel-traction train over 54.6 m. between East Dubuque and Prairie du Chein, U.S.A.

The highest speeds are those beyond human control, such as earth's orbital speed, 18,496 m. per sec.; solar motion, 12.1 m. per sec.; speed of light, approx. 186,300 m. per sec. A wind speed of 98 m.p.h. was recorded at Milldenhall on March 16, 1947.

Any speed in excess of that of sound (760 m.p.h. at sea level and decreasing to 675 m.p.h. at an altitude of 40,000 ft.) is called supersonic speed. Although rockets have exceeded 760 m.p.h., no human piloted vehicle reached the speed of sound until Sept. 6, 1948, when a U.S. piloted jet-propelled aircraft achieved 675 m.p.h. in a power dive from 40,000 to 30,000 ft.

Speedboat. Motor boat constructed for high speeds. It is usually of hydroplane design, to decrease resistance by displacing less water. Speedboats can be used safely only on calm water. In 1939 Sir Malcolm Campbell set up a water speed record of 141.74 m.p.h. on Lake Coniston in his speedboat Bluebird II, fitted with an aero engine. In 1950 S. Sayers, at Lake

Washington, U.S.A., reached 160-32 m.p.h. See Hydroplane; Motor Boat.

Speed Limit. Details of road speed limits imposed in the U.K. can be found under Motoring.

Speedometer. An instrument which records the speed of a motor vehicle. Usually a speedometer drive is incorporated in the transmission of the vehicle so that a flexible shaft drive may be taken to the spindle of the speedometer itself, which is mounted on the instrument board in view of the driver. In one form, the spindle carries a revolving magnet which exerts a drag on a light metal part separated from it by an air gap. This metal part may form the speedometer dial, being engraved with figures which come into line with a small aperture, or it may carry an indicator needle which moves over a stationary calibrated dial. In another form the spindle carries a small centrifugal governor; the movement of which by suitable levers and gearing is communicated to the needle which moves over a stationary dial. It is customary for speedometers to incorporate also a distance recording mechanism. This consists of numbered dials interconnected and set opposite to an aperture through which the mileage is read off. The rotation of the dials is effected by gearing from the spindle of the instrument.

Speedway Racing. Sport in which motor cycles race on a closed circuit. It originated in America in 1924, became popular in Australia soon after, and was brought from there to England in 1928. It is also popular in the British Empire and Holland. The machines used have no brakes or gears, and in the U.K. the engines must not exceed 499 c.c. Speeds of 65-70 m.p.h. are reached. The riders are in teams of six with two reserves. There are some 50 tracks of varying lengths in Great Britain. Speedway racing is one of the few major sports in Great Britain on which there is no betting.

Speedwell (*Veronica chamaedrys*). Perennial herb of the family Scrophulariaceae, native of Europe and Siberia. The opposite leaves are oval, strongly toothed, and stalkless, and the flowers, bright blue and shortly tubular, divide into four lobes, of which the upper and lower are broader than the side pair. There are only two stamens.

Speer, ALBERT (b. 1905). German architect and politician. Born at Mannheim, he was educated there, and studied architecture at

Karlsruhe, Munich, and Berlin. In 1931 he joined the Nazi party, and after Hitler's rise to power found favour as a designer of grandiose buildings. He planned the Reich chancellery in Berlin and the party headquarters at Nuremberg, becoming inspector-general of buildings in Berlin, 1937. After Todt's death in 1942 he became chief of war production, and was put in charge of reconstruction plans for bombed cities. By 1944 Speer was responsible for all German industrial output. Arrested in 1945, he faced the military tribunal at Nuremberg, was found guilty of war crimes, and on Oct. 1, 1946, sentenced to 20 years' imprisonment.

Spiegel, HAQUIN (1645-1714). Swedish poet. His literary fame rests chiefly on his Psalms, 1688, many of which are still sung in Swedish churches, and God's Work and Rest, 1685, a free translation of the Hexaëmeron of Arrebo (*q.v.*). He wrote also a history of the Swedish Church, 1707-08; and Paradise Lost and Refound, probably taking the idea from Milton. Spiegel was archbishop of Uppsala.

Speiss (Ger. *speise*, amalgam). Mixture of nickel, cobalt, iron, and other compounds. It collects at the bottom of the crucibles in which ores of minerals are being smelted with fluxes.

Speke. Locality of Lancashire, England. It is 7 m. S.E. of Liverpool by rly., and has an airport constructed in 1933 which was used for military purposes in the Second Great War and then for civil air lines. Factories in the district include one built at a cost of £1,125,000 by the ministry of Supply which was the world's biggest producer of penicillin and also turned out streptomycin. In 1946 Liverpool housing committee passed a scheme to develop Speke as a township with a pop. of nearly 22,000.

Speedwell. Blue flowers and toothed leaves of the common wayside plant

Speke, JOHN HANNING (1827-64). British explorer. Born in Somerset, May 4, 1827, he entered

the Indian army in 1844, and during his service travelled as far as Tibet. In 1854 he accompanied Sir Richard Burton into Somaliland. He and Burton made another journey from Zanzibar in 1857, pushing up to Lake Tanganyika; eventually Speke reached the Victoria Nyanza, having left Burton ill at Kaze. In 1862 Speke again made his way to Victoria Nyanza with J. A. Grant, and established the fact that the Nile is an outlet of the lake. He accidentally shot himself, Sept. 18, 1864. Consult his Journal of the Discovery of the Source of the Nile, 1863.

Speleology. The scientific study of caves. See Cave.

Spell (A.S. *spel*, a saying, story). Form of words equivalent to charm or incantation (*q.v.*). It is used in magic to conjure a spirit, to bewitch a person, to cure a disease. Spell, in the sense of a turn of work, is different, perhaps cognate with Ger. *spiel*, play.

Spelling. The use of letters to express the sound of words. In an ideal spelling system each sound would have only one sign to represent it, and each sign only one sound; there would be no pronunciation problems, and each letter would have a value when a word was spoken. In practice, however, spelling and pronunciation diverge, and the degree of divergence will depend upon several factors, including the literacy of the users of a language and the impact of other tongues upon it.

Thus English, which has over 40 sounds and 26 letters expressing these sounds unsystematically, is based upon a language, Anglo-Saxon, in which spelling and pronunciation were more nearly allied; but even in Anglo-Saxon one symbol represented several vowel sounds, and after the Norman Conquest the influence of the conquerors' different orthography and pronunciation made the divergence greater. The Anglicising of foreign words added greatly to the trend. The introduction of printing in the 15th century was a great stabilising influence upon English spelling, and the greater literacy which

J. H. Speke

printing brought created a conservative attitude to language.

In the 19th century there began to be demands by scholars and others for spelling reform, varying from the proposal for a completely new phonetic alphabet, by Bernard Shaw, to suggested modifications to lessen anomalies by Robert Bridges and philologists such as Furnivall. To a new phonetic alphabet there are practical objections, the greatest being that all printing machines would be rendered obsolete, and that the appearance of the new symbols would be an obstacle to an aesthetic appreciation of literature. Also, since pronunciation is in constant change, any phonetic system would in time become unphonetic.

Among European languages, Italian and Spanish are most nearly phonetic. See Orthography; Phonetics; Pronunciation. Consult Problems of Spelling Reform, Sir W. Craigie, 1944; Guide to Correct Spelling, W. O. Webster, 1947.

Spelt (late Lat. *spelta*). Variety of wheat (*Triticum sativum spelta*). Its brittle car easily breaks into short pieces, each of which bears a spikelet, and the grain cannot be properly threshed. Spelt was grown by the lake dwellers of Switzerland and the ancient Romans, and is still cultivated in central and S. Europe.

Spelter. This is a trade name for zinc (*q.v.*).

Spemann, HANS (b. 1869). German zoologist, born at Stuttgart, June 27, 1869. He was appointed professor at Rostock university in 1908, a director of the Kaiser Wilhelm institute of biology in Berlin, 1914; and took a chair in 1919 at Freiburg, where he was elected rector in 1923. He created and taught homology, the science of biologically identifying the function of organs seemingly widely different, and was an outstanding figure in the field of evolutionary mechanics. Experiments and numerous writings brought him the Nobel prize for medicine in 1935, the last one whose acceptance was tolerated by the Nazi regime. See Homology.

Spenborough. Urban district of Yorks (W.R.), England, 5 m. by rly. S.E. of Bradford. An amalgamation of Spenborough, Cleckheaton, Liversedge, Gomersal, Birkenshaw, and Hunsworth, it is in the borough constituency of Brighouse and Spenborough. It produces textiles, machinery, leather and plastic goods, wire, and carpets, and there are col-

lieries in the vicinity. The Red House at Gomersal is the Briarmains of Charlotte Brontë's Shirley. Market day, Sat. Pop. est. 34,500.

Spencer. Gulf of S. Australia. Lying between Eyre and Yorke Peninsulas, it is shallow, and receives no rivers of importance. Ports Pirie and Augusta are wheat-exporting harbours on its shores. Its maximum length and width are 200 m. and 80 m. respectively. Flinders sailed up the gulf in 1802, and discovered the great valley which runs N. from the head of the gulf to Lake Torrens.

Spencer, EARL. British title borne since 1765 by the family of Spencer. John Spencer (1734-83), grandson of the 3rd earl of Sunderland, was made a baron and a viscount in 1761, and Earl Spencer in 1765. His son, George John, 2nd earl, was first lord of the Admiralty, 1794-1801, and in 1806-07 a secretary of state. The 3rd earl is noticed below. Frederick, 4th earl (1798-1857), was a rear-admiral, afterwards serving as lord chamberlain and lord steward of the household. The 5th earl receives a separate entry. When he died childless in 1910 the title passed to his half-brother, Charles Robert (1857-1922), long a Liberal M.P. and during 1905-12 lord chamberlain. Albert (b. May 23, 1892) succeeded him as 7th earl. His seat is Althorp (*q.v.*), Northants, and an eldest son is called Viscount Althorp.

Spencer, JOHN CHARLES SPENCER, 3RD EARL (1782-1845). British statesman. Born in London,

3rd Earl Spencer, British statesman

May 30, 1782, eldest son of the 2nd earl, and educated at Harrow and Trinity College, Cambridge, he entered parliament in 1804, and was made a junior lord of the treasury in 1806, when his father was Home secretary. In 1827 his integrity and ability led to his selection as leader of the Whig opposition to Wellington, and in the Reform ministry of Grey, Viscount Althorp, as he still was, became in 1830 chancellor of the exchequer and leader of the house of commons, where he was largely responsible for carrying through the Reform Bill. His father's death in 1834 translated him to the lords, and Spencer withdrew from

politics and devoted himself to agriculture and the care of his estates. He died at Wiseton, Northants, Oct. 1, 1845. Consult Lord Althorp, E. Myers, 1890.

Spencer, JOHN POYNTZ SPENCER, 5TH EARL (1835-1910). British politician. Only son of the 4th

5th Earl Spencer, British statesman

earl, he was born in London, Oct. 27, 1835, and went to Harrow and Trinity College, Cambridge. For a few months he was in the commons, but in Dec., 1857, he

succeeded to the earldom. Already a leading sportsman and a commanding figure in society, he was in the household of the prince consort and the prince of Wales.

In 1868 Spencer became lord-lieutenant of Ireland, and he retained his office, though without a seat in the cabinet, until 1874. From 1880 he was lord president of the council; then in 1882 he went again to Ireland. A most influential convert, he followed Gladstone on Home Rule, and in 1886 was again lord president. From 1892 first lord of the Admiralty, he was Gladstone's choice as his successor in 1894, but when Rosebery was preferred he served him loyally. In 1902 Spencer became Liberal chief in the upper house, but by 1905 he was partially paralysed, and he took no further part in public life. He died Aug. 14, 1910. He had sold his fine library at Althorp to Mrs. Rylands in 1892. See Rylands Library.

Spencer, HERBERT (1820-1903). British philosopher. Born at Derby, April 27, 1820, he was privately educated. From 1837 to 1846 he was engaged in civil engineering, and he was sub-editor of *The Economist*, 1848-53. He opened his career as an author in 1842 with *Letters on the Proper Sphere of Government*, already noteworthy for their uncompromising individualism, and in 1850 published his first important work, *Social Statics*, in which an evolutionary theory of progress is clearly set forth. This was followed in 1855

Herbert Spencer, British philosopher

by the Principles of Psychology, in which such ideas are applied to the problems of mind.

Thus far, though evolution had provided the basis of his thought, he had dealt with many subjects in a fragmentary way. But having reached a conception of evolution as a universal process, he now perceived the possibility of making it the foundation of a comprehensive interpretation of life, mind, and society, and in 1860 he issued the prospectus of his *System of Synthetic Philosophy*. This system, which occupied him for 36 years, comprises ten volumes—*First Principles*, 1862; *Principles of Biology*, 2 vols., 1864; *Principles of Psychology*, 2 vols., 1872; *Principles of Sociology*, 3 vols., 1876–96; *Principles of Ethics*, 2 vols., 1889–92. Other works include *Education*, 1861; *The Study of Sociology*, 1873; *The Man versus the State*, 1884. Spencer had a nervous breakdown in 1855, and later became a complete invalid. He died at Brighton, Dec. 8, 1903.

In building his system, Spencer starts from the conception of philosophy as "completely-unified knowledge," and his purpose therefore is to reduce all knowledge to a coherent whole by taking the widest generalisations of the special sciences and establishing the universal truths under which the particular truths of such sciences may be subsumed. It is not the business of philosophy to explore the problems of absolute being, since, owing to its constitution, the human mind has no access to ultimate reality; the sphere of philosophy is that of phenomena only. Philosophy is a synthesis of the sciences.

Bases of Spencerian Philosophy

Having thus cleared the way by dismissing all ontological considerations, Spencer advances to his constructive task, which is the investigation of the processes by which the Unknowable Power manifests itself in the knowable universe, or, in other words, an interpretation of the universal transformation of things in terms of matter and motion. His basic principles are the persistence of force, with its corollaries, the transformation and equivalence of forces, the uniformity of law and the rhythm of motion; while his universal law is the law of evolution, which, restating his abstract formula in the simplest possible language, we may define as a change at once toward increasing diversity (differentiation) and

toward increasing definiteness and coherence (integration).

This law holds good of all phenomena, from those of the sidereal universe to those of social life; and having illustrated it in broadest outlines in *First Principles*, Spencer devotes his nine succeeding volumes to its demonstration in detail. In his *Biology* he traces the evolution of life, from its lowest cognizable forms up to man, through the continual interaction of organism and environment, incorporating in his law of equilibration (or the maintenance of a moving balance between the two) the Darwinian factor which he himself calls "the survival of the fittest."

In his *Psychology* he follows the concomitant evolution of mind from "the automatic actions of the lowest creatures," and in so doing undertakes the reconciliation of the conflicting schools of intuitionists and empiricists by showing that the intuitions of the individual are the results of the inherited and consolidated experiences of the race. In his *Sociology* he treats society as an organism, the changes of which are to be interpreted by the same universal laws of evolution.

In his *Ethics* he considers those "last stages in the evolution of conduct" which are "displayed by the highest type of being when he is forced, by increase of numbers, to live more and more in presence of his fellows," and here, as in the *Psychology*, affiliating empiricism to evolution, he exhibits our "moral intuitions," innate in the individual, as products of accumulated experiences of utility, at the same time advancing beyond the older utilitarians by deducing the laws of conduct from the conditions essential to the realization of the highest life. *See Ethics*; *Hedonism*; *Utilitarianism*.

Bibliography. *Autobiography*, 2 vols., new ed. 1926; *Lives*, H. Macpherson, 1900; J. A. Thomson, 1906; D. Duncan, 1908; H. S. R. Elliot, 1917; *Epitome of the Synthetic Philosophy*, F. H. Collins, 1890; *Introduction to the Philosophy of H. S. W. H. Hudson*, 1897.

Spencer, Stanley (b. 1891). British painter. Born at Cookham, Berks, he studied at the Slade school. He made his native village the setting for compositions inspired by the New Testament, e.g. *Nativity*, *Christ Bearing the Cross*, and *Resurrection* (the last two are in the Tate Gallery). These mystical works, which followed the example of the Old Masters in depicting sacred and

angelic characters in contemporary dress, excited great interest. A distinguished mural painter, Spencer executed designs for the walls of All Souls' Oratory, Burghclere, inspired by experiences on the Macedonian front during 1914–18. His canvas of *Travoy's Arriving with Wounded*, Macedonia, is in the Imperial War Museum. *Mending Cows*, and *Swan Upping* at Cookham, revealed a Pre-Raphaelite influence in structural details. Member of the New English art club 1919–27, Spencer was elected A.R.A. in 1932. Having resigned from the academy in 1935, he was in 1950 reelected A.R.A. and made C.B.E. in Jan., and elected R.A. in March. *See Art illus.*, p. 665.

Stanley Spencer,
British painter

Spender, John Alfred (1862–1942). British journalist. Born at Bath, he was educated there and at Balliol College, Oxford. During 1886–90 he was editor of the *Eastern Morning News*, Hull, and in 1892–96 assistant editor of the *Pall Mall* and *Westminster Gazette*.

J. A. Spender,
British journalist

In charge of the latter from 1896 to 1922, he became the close friend of Asquith, Grey, and Haldane, though his status as political editor depended also on the fine literary style which he impressed on his newspaper. In 1919 he went with Milner's mission to Egypt. After retiring, Spender devoted himself to writing and to efforts towards restoration of Liberal influence. His political studies included *The Public Life*, 1925; *Fifty Years of Europe*, 1933; *Life, Journalism, and Politics*, new ed. 1935; *Government of Mankind*, 1938; and he wrote notable biographies of Campbell-Bannerman, and of the 1st earl of Oxford and Asquith (with C. Asquith), 1932. He was created C.H. in 1937, and died at Bromley, June 20, 1942. He was the brother of Edward Harold Spender (1864–1926), biographer and journalist, and the uncle of Stephen Spender (v.i.). *Consult Life*, H. Wilson Harris, 1946.

Spender, STEPHEN (b. 1909). British poet and critic. Son of E. H. Spender, he was born Feb. 28, 1909, and educated at University College School, and University College, Oxford. In the 1930s he was talked of with W. H. Auden and C. Day Lewis as a leader of the Left-wing intellectuals in poetry. He could deal in clear-cut imagery, and showed acute awareness of suffering, especially when moved by the Spanish Civil War. Collections of verse included *The Still Centre*, 1939; *Ruins and Visions*, 1941; *Poems of Dedication*, 1946. Co-editor of *Horizon*, 1939-41, Spender published *The Burning Cactus*, 1936; *Forward from Liberalism*, 1937; *Life and the Poet*, 1942. *European Witness*, 1946, deals with post-war Europe. *World Within World*, 1951, was autobiographical. With A. L. Gili, he translated, 1939, some of the poems of Lorca (*q.v.*).

Stephen Spender,
British poet.

Spener, PHILIPP JAKOB (1635-1705). Founder of the German Pietists. Born in Alsace, Jan. 13, 1635, and educated at Strasbourg, Basel, Tübingen, and Geneva, he was appointed a public preacher at Strasbourg in 1663, and about three years later at Frankfurt,

Philipp Spener,
founder of Pietists

where he founded the Pietist sect, which aimed at fostering spiritual religion in place of the dry dogmatism of Lutheran preaching. He became court preacher at Dresden, 1686, but retired in 1691 to Berlin, where his meetings were condemned. He died Feb. 5, 1705.

Spengler, OSWALD (1880-1936). German philosopher. Born at Blankenburg, Belgium, May 29, 1880, he went to Germany to study political and social history, art, the major sciences, and mathematics, before becoming teacher in the last subject at Hamburg, 1908. Three years later he settled at Munich and devoted himself to the propagation of original politico-philosophical views. He died May 8, 1936. As a result of the great success of the

first vol. of his massive work, *Der Untergang des Abendlandes*, 1918, Spenglerian societies were set up throughout Germany and in France and England. This work, the second vol. of which appeared in 1927, was translated into English as *The Decline of the West*. Spengler regarded as inevitable a conflict between West and East. He saw the history of man as arranged in a series of cultures which completed identical cycles, the last of eight cultures being Western civilization. This had passed its height, and democracy was giving way to dictatorship. As fatalism of this kind took hold in post-war Germany, Spengler was acclaimed the prophet of revolution.

Spennymoor. Urban dist. of Durham, England. It lies about 6 m. S. of the city of Durham and has a rly. station. Industries include coal mines and iron and steel works. Until 1950 Spennymoor was the name of a parl. div., it is now in the co. constituency of Durham. Pop. 13,870.

Spenser, EDMUND (c. 1552-99). English poet. Born in London of humble parents, though he claimed connexion with the Spencers of Althorp, he was educated at Merchant Taylors' and Pembroke Hall, Cambridge. After graduating M.A. in 1576, he spent some months among kinsmen in Lancashire, where he enriched his poetic vocabulary from the local dialect, and fell in love with the Rosalind of *The Shepheardes Calendar*. A

From a portrait in the possession of the earl of Kinross

literary Cambridge friend, Gabriel Harvey, called him to London, and introduced him to the earl of Leicester and his nephew Philip Sidney, whose friend Spenser became. *The Shepheardes Calendar*

(*q.v.*), published in 1579, brought him immediate fame.

Already introduced at court by his powerful patrons, Spenser went to Ireland in 1580 as secretary to the new lord deputy, Lord Grey de Wilton, whose remorseless methods of imposing order won his admiration. After filling various posts, Spenser was rewarded with an estate of 3,000 acres in Cork. His ideas on English colonisation of Ireland are to be found in his prose work, *A View of the State of Ireland*. During these years a close friendship sprang up between Spenser and Raleigh, and it was at Spenser's castle of Kilcolman, about 1589, that the poet showed to his friend the first three books of *The Faerie Queene*, on which he had long been at work. Raleigh induced Spenser to come back to England with him and bring it to the notice of Queen Elizabeth. Gratified by the flattering references to herself, she awarded the author a pension of £50. The story of this visit to London is embodied in the fine pastoral *Colin Clouts Come Home Again*, 1595.

Marrying in 1594 Elizabeth Boyle, the story of whose wooing and marriage Spenser tells in his *Amoretti* and *Epithalamion*, he had made Ireland his home, when in 1597 an insurrection took place, Kilcolman Castle was burned, and one of Spenser's children, it is said, perished in the flames. He died in London, Jan. 16, 1599, a broken man, and was buried next to Chaucer in Westminster Abbey. The chief productions of his last years, in addition to further instalments of *The Faerie Queene*, were a collection of minor poems entitled *Complaints*, with the shrewd satire, *Mother Hubbard's Tale*; *Astrophel*, an elegy on Sidney's death; *Prothalamion*, with its refrain, "Sweet Thames, run swiftly till I end my song"; and *Four Hymnes*.

Spenser's poetry reflects a critical period in English life, the transition from the medieval to the modern world. More than any other he recovered and created the harmonies of English verse, and the influence of this poets' poet, as Lamb rightly calls him, is powerful throughout the history of English poetry. Though his daring experiments in language, his archaisms, provincialisms, and new coinages were only in part repeated by his successors, he enriched the language.

A true child of the Renaissance, possessed as few others were with a power of expressing sensuous beauty, he marvellously harmonises Italian and classic culture with

the moral gravity and spirituality of the English Reformation, and combines the ardour of chivalrous romance with the awakening national pride of the Elizabethan age. A Platonic idealist, he sees in chivalry and all human institutions the shadows of eternal truths. He is no realist, is seldom dramatic or humorous, lacks constructive power, and can be involved and prolix, but in his visionary world of luxuriant fancy he is supreme. He has a rare gift of verbal music, and the Spenserian stanza is one of the great metrical discoveries. *See* Faerie Queene.

Bibliography. Works, ed. J. C. Smith and E. de Selincourt, 1910; ed. E. Greenlaw, C. G. Osgood, and F. M. Padelford, 1939; Lives, R. W. Church, 1894; A. C. Judson, 1946; Critical Studies, W. L. Renwick, 1925; B. E. C. Davies, 1933; J. Spens, 1934; The Allegory of Love, C. S. Lewis, 1936; Evolution of the Faerie Queene, J. W. Bennett, 1943.

Spermaceti (Lat. *sperma ceti*, sperm of a whale). Waxy substance obtained from the oil contained in the large skull cavity of the sperm whale. Mainly cetyl palmitate, it is hard, translucent, pearly white, and unctuous. Separating at a low temperature from the sperm oil, it is repeatedly washed with hot water and boiling potash lye. Spermaceti is used for making candles and dressing textiles, and as an emollient in ointments.

Spermatic Cord. Cord-like mass of structures consisting of the vas deferens, arteries, veins, and nerves, which pass down from the abdomen to the testes.

Spermatophytes. Botanical term for seed plants, one of the two primary divisions of plant-life. They include all those species which produce true seeds, containing an embryo which develops directly into a plant resembling its parent. It comprises two groups: the Angiosperms, or higher flowering plants, whose seeds are enclosed in fruits; and the Gymnosperms, whose seeds are not enclosed, but borne on special leaves or branches. *See* Botany; Cell; Plant.

Spermatozoon (Gr. *sperma*, seed; *zōon*, animal). Male germ cell. In the lowest form of life the spermatozoon and the female cell, or egg, are not dissimilar, but in higher forms the spermatozoon becomes a highly specialised active locomotor cell, and the female egg or ovum becomes a larger, more passive cell. The spermatozoon is provided with a head, body, and

tail, the first containing a nucleus of chromatin, the body the centrosome. The tail is a cytoplasmic thread, and provides the power for movement. *See* Embryology; Fertilisation.

Sperm Oil. Oil obtained from the cachalot or sperm whale. It is a useful lubricating oil because it does not readily become gummy or acid. *See* Whale.

Sperm Whale (*Physeter catodon*). Large Cetacean, also known as the cachalot (*q.v.*).

Sperrin. Range of mountains in N. Ireland. They extend E. to W., mainly between Strabane, Tyrone, and Draperstown, Londonderry, and in Sawel Mt. reach a height of 2,240 ft.

Spessartite. Rather rare, manganiferous variety of garnet (*q.v.*), possessing a deep red colour, occurring occasionally in acid igneous rocks like granite, and in lowly metamorphosed sedimentary rocks such as whetstones.

Spey. Second largest river in Scotland and the swiftest in the kingdom. Rising in the hills between Lochs Lochy and Laggan, it flows E. and N.E. through Inverness-shire and Morayshire, forms part of the boundary between the latter county and Banffshire, and enters the Moray Firth at Kingston. It is 110 m. long, and has valuable salmon fisheries. The district through which it flows is known as Speyside, the chief industry of which is whisky distilling.

Speyer or **SPEIER.** German name of the capital of the Palatinate, also known as Spire (*q.v.*).

Speyer, EDGAR (1862-1932). Anglo-German financier and collector. Born in Frankfurt-on-Main, Sept. 7, 1862, he was educated there, and joined his father's financial firm. In 1887 he took over the direction of the London house and in 1892 became a naturalised British subject. His firm was interested in the London underground railways among other undertakings. One of the founders of Whitechapel Art Gallery, and a notable benefactor of charities, Speyer was created a baronet in 1906 and a privy councillor in 1909. In 1914 he retired to Germany, and in 1921 was deprived of British nationality and honours on the ground of disloyalty to the king and unlawful communication with the enemy during the First Great War. He died Feb. 16, 1932.

Spezia (Ital. La Spezia). City and seaport of Italy, in the prov. of Spezia. It is situated on the Gulf of Spezia in the Riviera di Levante, 56 m. by rly. S.E. of

Genoa, amid fort-crowned hills, and was made the chief naval harbour of the country in 1861. It has an arsenal, docks, shipyards in which some of the largest Italian warships have been built, a school of navigation, barracks, and artillery, torpedo, and electrical works. Sailcloth, cables and other iron goods, furniture, and leather goods are manufactured; there is trade in olive oil, wine, fruit, and marble. Spezia is a sea-bathing and winter resort. Shelley was drowned in the gulf in 1822. In the Second Great War the harbour was heavily damaged in demolition raids and the cathedral suffered severely by bombing before Spezia fell on April 24, 1945, to the Allied 5th army. Pop. (1936) 106,119.

Spezia, SPETSÆ, OR PETSÆ. Island of Greece. Lying at the mouth of the Gulf of Nauplia, it is about 10 m. S.W. of Hydra and has an area of about 12 sq. m. On it is a small port of the same name.

Sphaerella (dim. of Lat. *sphæra*, a globe). Genus of single-celled Algae, more generally known as Haematococcus, but occasionally as Protococcus.

Sphagnales or **SPHAGNACEÆ** (Gr. *sphagnos*, moss). Order of mosses, consisting of the single genus *Sphagnum*, or bog moss (*q.v.*). *See* Moss.

Sphalerite or **BLENDE.** Chief ore mineral of zinc. Crystallising in the isometric-tetrahedral class, its atomic structure is face-centred cubic, similar to diamond. Although tetrahedral crystals occur, sphalerite is generally found in massive forms, either granular or compact. It varies in colour from yellow to brown and black; more rarely it may be green, red, or nearly colourless. Specific gravity is 4±0.1. Lustre is resinous to adamantine. In addition to zinc sulphide, it may contain iron up to 20 p.c., manganese, cadmium, mercury, rarely lead and tin, or traces of indium, gallium, thallium, silver, and gold.

Zinc sulphide (ZnS) occurs in two forms, sphalerite, stable at temperatures below 1020° C., and wurtzite, stable at higher temperatures. ZnS is deposited as sphalerite from alkaline solutions. Both forms are precipitated from acid solutions, the amount of sphalerite increasing with temp. and that of wurtzite with acidity.

Sphalerite is very closely allied with galena (*q.v.*). There is only one important field known where the deposit is worked for zinc only, namely, at Franklin Furnace, N.J. Most zinc deposits are found

in veins and lodes in igneous, sedimentary, and metamorphic rocks, or as replacements and disseminations in sedimentary rocks, especially limestones and dolomites. Commonly associated are pyrite, chalcopyrite, galena, calcite, barytes, fluorite, etc. Sphalerite is widely distributed; the most notable deposits occur at the Sullivan Mine, B.C.; Broken Hill, N.S.W.; Bawdwin mines, Upper Burma; in Oklahoma; and at Franklin Furnace.

Both names are derived from words suggesting deception (Gr. *sphaleros*, treacherous; Ger. *blenden*, to deceive) because the mineral often resembles galena but is found to contain no lead. See Zinc Ores.

Sphene (Gr. *sphēn*, wedge). Name of a variety of titanite (*q.v.*).

Sphenodon (Gr. *sphēn*, wedge; *odontes*, teeth). Lizard-like reptile of New Zealand, known to the Maoris as Tuatara, and now called

Sphenodon. Nocturnal reptile, somewhat similar to a lizard, that lives in New Zealand
W. S. Berridge, F.Z.S.

scientifically *Sphenodon punctatum*. It is the only surviving representative of the order Rhynchocephalia (snout-headed) of the reptiles. It differs from the lizards in having the quadrate bone, to which the lower jaw is attached, immovable; while the bones of the vertebrae are hollowed at both ends. The mandible is beak-like, and there is a pineal body, or rudimentary third eye, in the top of the skull. The skin is tubercled, and a crest of small spines runs along the middle line of the back and tail. The sphenodon is about 20 ins. long, and its colour is usually dark olive with yellow dots. It lives in burrows and comes out at night to feed on insects, worms, and other small creatures. The eggs are deposited in holes in the sand, and apparently do not hatch until about a year later. It is very sluggish in its movements, and seems to have been exterminated on the main islands of the New Zealand group.

Sphenoid Bone (Gr. *sphēn*, wedge; *eidos*, shape). Bone of complicated shape forming part of the base of the skull. A depression on

the upper part contains the all-important pituitary gland.

Sphere. Solid bounded by a surface which is everywhere equidistant from a fixed point, its centre. Every plane section of a sphere is a circle, and those made by planes passing through the centre are known as great circles. The shortest line joining any two points on the surface of a sphere is the arc of the great circle passing through the two points. The surface of a sphere is four times the area of a great circle, *i.e.* $4\pi r^2$ where r is the radius of the sphere. The sphere is the largest solid of given surface, and its volume is $\frac{4}{3}\pi r^3$, or two-thirds that of the circumscribing cylinder.

Sphere, THE. London weekly illustrated periodical. Established Jan. 26, 1900, by Hugh Spottiswoode of the firm of Eyre and Spottiswoode, and Clement Shorter (*q.v.*), who edited it from the start until 1926, it at once took rank with the foremost papers of its kind, being notable for excellence of illustrations, explanatory diagrammatic drawings, the high quality of its literary pages, and the piquant character of its Literary Letter. In 1912 it incorporated Black and White, in 1933 The Graphic. The Sphere is one of a group of associated high-class illustrated periodicals of which the chief is the Illustrated London News (*q.v.*).

Spherical Harmonics. In mathematics, certain functions which are of fundamental importance in the investigation of gravitational, electrical, and other attractions. Spherical harmonics depend upon a differential equation known as Laplace's equation, the method being due to the French mathematician. By means of this Laplace was able to calculate the attraction of the earth, and Gauss to formulate a theory of terrestrial magnetism.

Spherical Trigonometry. Branch of mathematics concerned with spherical triangles. Such a triangle is one formed on the surface of a sphere by the mutual intersections of three great circles. Such triangles have the same definitions of right-angled, equilateral, isosceles, etc., as triangles in plane trigonometry. The solution of any spherical triangle may be made to depend on that of a right-angled spherical triangle. See Triangle; Trigonometry.

Spheroid. In geometry, a solid generated by the revolution of an ellipse about one of its axes. An oblate spheroid is generated with the minor axis as the axis of rotation, and a prolate spheroid round the major axis. See Ellipsoid.

Sphinx (Gr. *sphingēin*, to strangle). Composite human and animal form which appears in ancient art. It is of Egyptian origin, and as such has the body of a lion and a human or animal head. Human-headed sphinxes are called androsphinxes; those with the head of a ram, criosphinxes; and those with a hawk's head hieracosphinxes. Assyrian and Babylonian sphinxes have wings, and the Greek sphinx consists of a winged lion with a female bust.

In Egyptian hieroglyphs the sphinx bears the name of Neb, or lord, and Akar, or intelligence, the whole figure symbolising force and intellect. For this reason large stone sphinxes were erected by the Egyptians as symbols of monarchy, the head of the reigning king being placed upon a lion's body (to symbolise strength) and the face bearded.

The oldest example, the Great Sphinx of Gizeh, in lower Egypt, is a recumbent image of a man-headed lion, hewn out of a rocky knoll near the pyramid of Khafra. It is 187 ft. long, the head 30 ft. long, the face 14 ft. wide, and the height to top of the head 66 ft. The features, once painted red, were marred by medieval Mameluke vandalism. Portions of the beard and uraeus are in the British Museum. In front of the breast Thothmes IV set up a granite slab, mentioning Khafra's name, to commemorate the digging of the image out of the drifted sand. It was worshipped as Harmachis, and there are remains of an open-air temple between the paws, with an altar of Roman date.

The next oldest sphinxes, a granite pair 7 ft. long, bear the name of Pepi I, of the VIth dynasty. Several examples from Tanis are attributed to Amenemhat III. Under the New Empire avenues of so-called sphinxes, mostly recumbent rams or ram-headed lions, were erected at Thebes from temple to temple. An unfinished colossal sphinx of that age still remains in the Gebel Silsila quarries. The Egyptian sphinx was deemed to represent a real creature fabled to haunt the deserts. Sometimes it is hawk-headed or jackal-headed; winged and female forms are rare. According to Greek mythology the

sphinx propounded riddles, strangling those who failed to solve them, but slaying herself when Oedipus offered the solution.

The pair of bronze sphinxes at the base of Cleopatra's Needle on the Thames Embankment, London, are modern work, by G. Vulliamy. See Egypt; Hittites; Karnak; Pyramids.

Sphygmograph (Gr. *sphymos*, pulsation; *graphein*, to write). Instrument by which the beating of the pulse is recorded on a strip of paper. The characteristics exhibited by the tracing afford valuable information to the physician.

Spica, OR ALPHA VIRGINIS. Principal star in the constellation of the Virgin. It is of the first magnitude, an eclipsing and spectroscopic double star. The two components of the double appear to revolve about their common centre in four days at a speed of more than 80 m. a sec. Each component is about 700 times as bright as the sun.

Spice Islands. Historic name for the group of spice-yielding islands in Indonesia, now known as the Moluccas (*q.v.*).

Spices (Old Fr. *espice*, from Lat. *species*). Productions of plants that are aromatic to the smell and pungent to the taste. The spices are collected from different parts of plants. The most used are allspice, the berries of the pimento; cinnamon, the bark of a small evergreen tree of Ceylon; clove, the dried calyx and flower buds of a myrtle; ginger, the root of a tropical plant, and nutmeg, the kernel of another; mace is the covering of nutmeg. Ground spices are used as flavourings. Consult In Quest of Spices, S. E. Howe, 1944.

Sphinx of Gizeh, from the east. This gigantic figure, hewn from the living rock, is of unknown age and lay for centuries half buried in the sand

Spider. Well-defined order (Araneida) of the class Arachnida, which also includes scorpions, mites, harvestmen, etc. The class belongs to the large series of Arthropods (jointed-footed animals), but differs from the others in having no antennae.

The spider's body is divided into two parts: (1) The head and thorax, fused into one piece (the cephalothorax), and (2) the abdomen, usually all of one piece, and only rarely with hints of segmentation. Between these two parts there is typically a narrow waist. The region corresponding to the head bears two pairs of mouth parts: (a) a pair of two-jointed poison-jaws or chelicerae, and (b) a pair of sensitive, usually six-jointed pedipalps.

All spiders are poisonous, but the bite is not severe except in a few tropical forms. The poison of the bird-catching spider (*Mylgale*) kills a bird in a few minutes.

In male spiders the tip of the pedipalp is complicated; it becomes a reservoir for spermatozoa at the pairing season, and is used to transfer them into the female, where they fertilise the eggs just before these are laid. In the main, the pedipalps are touch-organs, and tactile sensitiveness is carried to perfection in the spiders.

On the top of the head are several pairs of simple short-sighted eyes. From the region corresponding to the thorax there arise four pairs of seven-jointed legs, ending in minute curved claws, by means

of which spiders grip the surface on which they creep. At the end of the abdomen there are 4-6 minute appendages transformed into spinnerets, from which the silken threads emerge. Each spinneret resembles the rose of a watering-can, for it bears numerous minute tubes (spinning-spools) through which the silk issues. There may be hundreds of these spinning-spools, and each is connected with an internal gland which makes the silk. The gland is enclosed in a muscular envelope, the contraction of which, acting like a syringe, forces the liquid silk down a duct and out at a spinning-spool. There are sometimes three kinds of glands, producing different kinds of silk, and it rests with the spider to use more or fewer at one time, thus adjusting the thickness of the thread. The thread is a fusion of many jets of liquid silk, which solidifies instantaneously on exposure to air.

A small minority of spiders (the bird-catching spiders, trapdoor spiders, etc.) breathe by two pairs of lung-books; all the rest breathe by two lung-books and two or four groups of air-tubes or tracheae like those of insects. Through an external slit, flush with the skin, air enters the compartments of the lung-book; in the partitions between the compartments the blood circulates and is purified. As to the other organs of the body, there is a muscular region near the beginning of the food-canal, for spiders suck the juices of the insects on which they mainly depend; there is a heart along the mid-dorsal line of the abdomen; there are digestive glands and structures analogous to kidneys.

What comes out of the hatched egg of a spider is practically a

Spider. 1. Full-grown garden spider. 2. South American trapdoor spider, at the mouth of its burrow. 3. House spider, devouring a bluebottle

miniature of the adult. In other words, there is no metamorphosis. The young spiders grow quickly and moult frequently. Spiders are characteristically terrestrial, but a few occur in fresh water, notably the water spider (*Argyroseta aquatica*), which makes a web under water and fills it with air.

When a spider is in danger of losing its foothold, it pays out a drag-line of silk. This is the origin of the irregular snare as in the house spider (*Tegenaria domestica*), and of the beautifully regular web, and the silk is also used by the females to make a cocoon for the eggs, and by some small spiders to form gossamer parachutes on which they are borne by the wind.

The males are usually smaller, often much smaller, than the females, and may be brighter in colour. Spiders are preyed upon by birds, lizards, wasps, and other enemies. See Animal colour plate; Arachnida; Bird-Catching Spider.

Bibliography. History of the Spiders of Great Britain and Ireland, J. Blackwell, 1861; Life of the Spider, J. H. Fabre, Eng. trans. 1912; British Spiders, T. H. Savory, 1926; Spiders and Allied Orders of the British Isles, T. H. Savory, 1928; Comity of Spiders, W. S. Bristowe, 2 vols., 1939-41.

Spider Monkey (*Ateles*). Genus of American monkeys. They are notable for their attenuated limbs, slender bodies, and long prehensile tails. Marvellously agile, they swing from bough to bough,

Spider Monkey. The black-faced species

making use of their prehensile tails. There is a large number of species, all found between Mexico and Uruguay, and in Brazil the natives use them for food.

Spiderwort (*Tradescantia*). Genus of perennial herbs of the family Commelinaceae, natives of America. They vary considerably in form and habit. The three sepals are sometimes coloured other than green; the three petals are equal, oval, blue, purple, rose, or white. Some tropical species are in cultivation in hot-houses and green-houses; but the best known is the hardy Virginian spiderwort (*T. virginiana*) of southern N. America,

Spiderwort. Leaves, buds, and flowers of the Virginian species

which has narrow leaves with purple veins, woolly sepals, and rich purple-blue petals.

Spiegel or **SPIEGEL IRON** (Ger. *Spiegeleisen*). White cast iron used in the manufacture of steel by the Bessemer process. It contains 15 to 30 p.c. of manganese and about 5 p.c. of carbon and is added to control the amounts of these elements present in the finished steel.

Spike. Form of inflorescence in which the flowers are all stalkless, and attached to a common elongated axis. See Inflorescence; Sabadilla.

Spike Island. Small island of co. Cork, Eire. It lies in Cork Harbour, and on it during 1847-85 was the principal Irish convict prison. Many prisoners were employed in the construction of the royal dockyard and fortifications.

Spikenard (*Nardostachys jatamansi*). Perennial herb of the family Valerianaceae, native of the Himalayas.

Sometimes called nard, it has a short, thick, spindle-shaped rootstock, very fragrant, which constituted the spikenard of the ancients. The lance-shaped or spoon-shaped leaves are tufted, and the small, rosy-purple flowers are gathered into dense heads.

Spikenard. Left, leaves and flower heads; right, rootstock

Spilite. Type of basaltic rock which is rich in soda. Spilites are commonly associated with sediments laid down in elongated subsiding troughs (geosynclines), and because of their eruption beneath the sea, they commonly show pillow structure. See Igneous Rocks; Pillow Lava.

Spilsbury, SIR BERNARD HENRY (1877-1947). British pathologist. Educated at University College school, Manchester grammar

school, and Magdalen College, Oxford, he received his medical training at S. Mary's Hospital. After doing research work on bacteriology, he turned to the study of morbid anatomy and concentrated on forensic medicine. Scotland Yard called in his aid in connexion with many murder cases, one of the earliest being that of Crippen. Knighted in 1923, he was honorary pathologist to the Home office for many years until his death by his own hand, Dec. 17, 1947.

Sir Bernard Spilsbury, British pathologist

Spilsby. Market town of Lindsey, Lincs, England. It is 17 m. N. of Boston and 12 m. W. by N. of Skegness. The chief buildings are a 14th century church with monuments of the family of the earl of Ancaster, and the grammar school. In the market place is a statue of Sir John Franklin, who was born here. There is a trade in agricultural produce. Pop. 1,372.

Spin. Condition obtaining in aeronautics when an aircraft engine stalls, so reducing flying speed. The aircraft goes out of control and the nose drops, causing the machine to fall earthwards nose first and rotating about its longitudinal axis. There are three kinds of spin: (a) normal, in which the rotation of the aircraft may be clockwise or anti-clockwise with the nose pointing downward and describing a small circle, and the tail a larger one; (b) flat spin, in which the aircraft after spinning about eight rotations, begins to flatten out, its fore and aft axis becoming more horizontal; (c) inverted spin, in which the aircraft spirals upside

down, in a combination of looping, rolling, and yawing. In any kind of spin, the fall seldom exceeds 70 m.p.h., and if the spin starts at sufficient height there is usually time for the pilot to straighten out by centralising the rudder.

In ballistics spin is the rotation of a projectile in flight. According to the turn of the rifling, spin is to right or to left. The rate of spin decreases during the projectile's passage to the target, starting at 10 p.c. for the first second of flight.

Spilsby, Lincolnshire. Parish church of St. James. See previous page

Spinach (*Spinacia oleracea*). Annual herb of the family Chenopodiaceae. This native of the Oriental region was introduced to Great Britain in 1568. The seed should be soaked in water for at least twelve hours, and then sown thinly, at desired intervals from Feb. onwards, in moist, deep soil, where the plants are to remain. As the leaves of the spring-sown plants are ready to be picked in from six weeks to two months after sowing, spinach is a good catch crop. Sulphate or nitrate of soda, or sulphate of ammonia, may be applied to the surface of the soil when the plants are about three inches in height. Spinach is one of the most easily grown and profitable vegetables. *Pron.* spinn-idge.

Spinado. Card game, a variation of Newmarket. The holder of the ace of diamonds, when he has the lead, may use it as a stop to any sequence when he calls "spin." He may then start another sequence of his own, and so be able to play a card corresponding to one of those in the lay-out, which is the object of the game, as it entitles him to all stakes upon that card. In other respects the game is played like Newmarket.

Spinal Column. In vertebrate animals, a series of hollow, connected bones enclosing the spinal cord, and supporting the trunk. In the human species the spine or "backbone" is composed of 24 separate bones or vertebrae. During the development of the skeleton there are 33 vertebrae, but of these five unite into one mass, forming the sacrum, and below the sacrum are four very small vertebrae, which become more or less united as age advances, forming the coccyx. The separate vertebrae are connected with each other by cartilaginous disks.

The spine is not a straight column, but is curved forwards in the cervi-

cal and lumbar regions, and backwards in the dorsal and sacral regions. The ligaments and cartilages which unite the vertebrae permit of movements which are limited between any two vertebrae, but, extended over the column as a whole, permit of a considerable degree of rotation of the body and bending laterally or backward or forwards.

DISEASES OF THE SPINE. Curvature of the spine is most frequently due to rickets in childhood, or bad habits during adolescence when the child is growing rapidly, such as continuous stooping, which may result from sitting at too low a desk at school. Besides rickets and weakness during growth in adolescence, curvature of the spine may follow disease or dislocation of the hip-joint or disease of the knee-joint, which causes shortening of the leg or disease affecting the bones of the spine.

Spinach. Leaves and flowers of the table vegetable; inset, the two forms of leaf

The treatment of curvature of the spine in children consists, in the first place, of correcting all errors of position, and providing suitable desks and chairs. Appropriate gymnastic exercises and massage are helpful. The general health must be maintained, and any condition such as anaemia corrected. In severe cases spinal supports may be employed, but these have the effect of weakening the muscles of the back from disuse, and should be employed as little as possible.

Tuberculous disease of the spine, spinal caries, Pott's disease, or angular curvature, is an affection occurring at any age, but most frequently in children under the age of 10. The anterior surface of one or more of the vertebrae becomes attacked and eroded, with the result that the bodies of the vertebrae fall together, and a sharp angle is developed in the back. The symptoms of caries of the spine are pain, rigidity when certain movements are attempted,

and deformity of the back. In some cases the spinal cord becomes involved and paralysis may follow. As regards treatment, the essential feature is to immobilise the affected vertebrae, and relieve them of the weight of the body. This may be effected by keeping the child in the recumbent posture, placing it in a special apparatus, known as a Phelps box, or by applying a plaster jacket from the pelvis to the chin and neck, portions being cut out where a support is not needed. These measures as a rule have to be continued for six months or a year or more. During that time the general health should be carefully attended to, and the child should be as much as possible in the open air. Disease of the spine may also be the result of syphilis or rheumatism.

The spine serves two functions. It provides a firm though not absolutely rigid pillar, which enables the body to be maintained in the upright position, and the arches attached to the vertebrae form a continuous canal, in which the spinal cord is lodged and thereby protected from injury. Its average length is 28 ins. in the male, and 27 ins. in the female. Above, it supports the skull, and on the sides it supports the ribs. Below it rests on the sacrum, which forms part of the pelvic girdle.

Spinal Cord. Column of nerve fibres and cells, continuous above with the brain, which extends from the lower border of the foramen magnum or large aperture in the base of the skull to the lower border of the first lumbar vertebra, where it terminates in a slender filament. It occupies the canal of the spine or backbone, and is surrounded by prolongations of the membranes covering the brain, namely the dura mater, arachnoid, and pia mater.

A section of the cord shows that it is composed of white matter and grey matter. The white matter, which is situated externally, consists of nerve fibres mainly running

Spinal Column and skull

lengthwise through the cord, and connected by a supporting material. The grey matter consists of nerve fibres, most of which are very fine, nerve cells, and a delicate supporting network. Thirty-one pairs of nerves are given off from the spinal cord, each nerve being formed from an anterior and posterior root which unite and pass out between the bony arches of the vertebrae. The spinal cord consists of many different strands of nerve fibres, and in the grey matter are nerve centres which take part in the discharge of various physiological functions. Through these strands of nerve fibres impulses are conveyed from the skin and other parts to the brain or spinal nerve centres, and through other strands go impulses to the peripheral muscles. Disease or injury of the spinal cord often leads to paralysis. See Disseminated Sclerosis; Locomotor Ataxia; Myelitis; Paralysis.

Spinal Cord and Brain. 1 and 2. Dura mater. 3. Meningeal arteries. 4. Superior swelling. 5. Middle swelling. 6. Inferior swelling. 7. Spinal nerves.

peripheral muscles. Disease or injury of the spinal cord often leads to paralysis. See Disseminated Sclerosis; Locomotor Ataxia; Myelitis; Paralysis.

Spindle Tree (*Euonymus europaeus*). Small tree of the family Celastraceae, native of Europe,

Spindle Tree. Fruits dried and split, revealing the orange seeds

W. Siberia, and N. Africa. It grows to a height of about 20 ft. only, and has smooth grey bark and four-angled twigs. The opposite, lance-shaped leaves have obscurely toothed edges, and the minute flowers are greenish white. The fruits are four-lobed capsules of crimson hue, which open to disclose the orange jackets (arils) of the few large seeds. The hard,

tough wood is of use for making small articles. See Celastraceae.

Spine. Backbone of an animal. Its full name is the Spinal Column (*q.v.*).

Spine. In botany, a sharp process borne by plants for defensive purposes. Distinct from a thorn in that it possesses no vascular tissue, it is most frequently found on the margins of leaves, as in the thistle and holly, but occasionally whole leaves are modified into spines, *e.g.* the cactus. The word is also applied to the protective outgrowths on the backs of hedgehogs and porcupines. See Hair; Thorn.

Spinel. Group of minerals having the formula $XO.Y_2O_3$ (when X = magnesium, divalent iron, zinc, and manganese; Y = aluminium, trivalent iron, and chromium). There are many species, the most important being spinel, $MgO.Al_2O_3$; hercynite, $FeO.Al_2O_3$; gahnite, $ZnO.Al_2O_3$; magnetite, $FeO.Fe_2O_3$; franklinite, $(Fe, Zn, Mn).O.(Fe, Mn)_2O_3$; chromite, $FeO.Cr_2O_3$. All spinels are characterised by isometric symmetry, octahedral form, and similar atomic structure. Colour varies considerably from black magnetite and chromite through green gahnite to clear varieties used as gemstones, namely spinel ruby, balas ruby, and rubicelle. The Black Prince's ruby in the British imperial crown is a spinel. Spinels are common accessories in igneous and metamorphic rocks, and in residual deposits. Gem varieties come from Ceylon, Burma, Siam, and Afghanistan.

Spinnet (It. *spinetta*, little thorn). Keyboard instrument of the harpsichord type, but smaller. Its strings were plucked by quills, whence probably the name, though there is some evidence that this commemorates an Italian maker, Spinetti (*fl.* c. 1500). The spinnet varied in compass from under four to just five octaves. Early examples were small enough to be placed upon a table when in use, but later and larger specimens stood on legs. It was a favourite household instrument in the 16th–18th centuries, the cases being frequently embellished with paintings and occasionally with precious stones. See Virginal.

Spinnaker (A.S.). Sail set out from the weather side of a vessel and opposite the mainsail. It is used largely in racing yachts. The spar which takes it at the foot is called the spinnaker boom. Mostly the spinnaker is set when the vessel is running before the

Spinnaker. Stern view of a racing cutter showing her sails. A. Topsail. B. Mainsail. C. Spinnaker

wind. A spinnaker topsail is a topsail set on a jack yard or short boom. See Ship.

Spinning. Art of drawing, twisting, and combining animal or vegetable fibres into continuous threads. The simplest method of hand-spinning is with the rock or distaff, a system of most use in treating comparatively long fibre, like flax or worsted. The dressed or combed material, fashioned into a twist by hand, is fastened to the spindle. The spindle is given motion by a quick rub against the thigh with the right hand, and is suspended by the thread, thus acting as a bob or weight for twisting the cord of fibres, the thread being meanwhile elongated between the hands.

Spinnet. A 16th cent. example of this keyboard instrument

The spinning wheel, in an early form, consisted of a stool bearing a large and heavy wheel and a support to carry the spindle, which was belt-driven from the fly-wheel. The spinster maintained the motion of the wheel by strokes of the right hand, and with the left stretched the cord of roving or prepared fibre, first twisting the cord and then winding it on the spindle. The improved or Saxon wheel was fitted with a treadle to drive the fly-wheel, and the spindle was fitted with a flyer, a leg of metal pivoted on top of the spindle and moving round its circumference. At the foot of the

flyer was an eye through which the thread could be led, and the bobbin around the spindle was dragged round by its motion. Thus both hands of the spinster were liberated and, the flyer supplying the necessary drag, the twisting of the cord and the winding-on of the yarn continued simultaneously.

The spinning wheel formed the basis of Hargreaves's jenny (*v.i.*), which was at first an apparatus for enabling one person to spin sixteen or more threads at once. Lewis Paul of Birmingham in 1738 invented the means of superseding human fingers in drawing the sliver, or roving, out finer. He passed the rope of prepared material through pairs of rollers, each pair running faster than the preceding ones, so that the sliver was delivered at a faster rate than it was fed, and this principle of roller drawing, or drafting, is the fundamental one in making disconnected fibres into a continuous yarn. In Arkwright's machine, 1769, known as the water-frame, Paul's invention was first brought into successful use.

Cap and Ring Systems

The flyer system of continuous spinning, although giving technically perfect results, is subject to the one grave disadvantage that the vibration set up by the revolution of the flyer-leg limits the speed at which a spinning frame can be driven, and therefore the output. Other means have hence been sought of securing the light drag upon the cord that will enable twisting and winding to go on simultaneously. The cap system has been introduced for the less hairy wools; the stationary projecting cap on top of the quickly rotating spindle creates enough friction for the purpose without too much disturbance of the fibre.

The ring system is employed chiefly for cotton, and especially to make single warp yarn. In this system the spindle revolves at high speeds (5,000-10,000 r.p.m.) within rings or annular openings made in a steel rail or shelf. The rail is given an up-and-down motion which guides the yarn in winding-on. Its rings project above the surface of the rail and are made with high accuracy. Over the lip of the ring a light bent wire called the traveller is hooked, and the yarn passes under the wire which travels around the ring, exerting light friction upon the thread.

Upon any of these continuous spinning machines the cord of rovings prepared in the preliminary processes is drawn from large

bobbins through pairs of front and back rollers, which draft or reduce the roving in accordance with the gearing. The amount of twist imparted is settled by the ratio of the speed of the spindles, and, as twisting impedes the process of winding-on, more twist than necessary is not given. Spinning frame minders supervise two or three sides of frames, which are set back to back and carry some 200 or more spindles each, and the minder has the task of rejoining broken threads and preventing the production of waste.

The finest cotton and some wool yarns are spun on the mule, a machine which performs the operations of drawing-out, twisting, and winding on to a bobbin successively, instead of simultaneously. Some linen yarns are "wet-spun," i.e. the roving is passed through a bath of hot water as it is being drawn out, and the result is a yarn with fibres cemented together. *See* Arkwright, Sir R.; Blanket; Bobbins; Cotton; Distaff; Loom; Mule; Silk; Weaving; Yarn.

Spinning Jenny. Machine for spinning invented by James Hargreaves, of Blackburn. It utilised the same principles as are embodied in the modern machinery. The jenny was turned by hand and spun few threads at a time; it was improved on by Arkwright and Crompton, and is now obsolete. This was one of the machines that inaugurated the industrial revolution. *See* Hargreaves, J.

Spinola, Ambrosio, Marquis de los Balbasses (1569-1630). Spanish soldier. Of Genoese birth,

Ambrosio Spinola,
Spanish soldier

he entered the Spanish service in 1602, seized Ostend in 1603, and in 1604 became commander-in-chief in Flanders, conducting a campaign which, though successful from a military point of view, ruined him financially. The capture of Breda, 1625, his greatest exploit, closed his military career. Sent to Italy in 1629, he died Sept. 25, 1630.

Spinoza, Baruch, or Benedict de (1632-77). Dutch philosopher. Born at Amsterdam, Nov.

Baruch Spinoza,
Dutch philosopher

24, 1632, of Portuguese-Jewish parentage, he at first studied theology, but his unorthodox views brought the hostility of the rabbis and led in 1656 to his

excommunication. An attempt having been made on his life by one of his co-religionists, Spinoza left Amsterdam, and devoted himself to philosophy. He refused a professorship at Heidelberg lest it might interfere with his studies and obtained a living by polishing lenses. From 1663 he lived at The Hague until he died, Feb. 21, 1677. His character commands the greatest admiration, for he was not only persecuted but suffered from consumption and existed in dire poverty. He bore all with fortitude and dignity, and his integrity allowed no compromise.

Spinoza's philosophy is based upon that of Descartes, but set forth according to a rigorously geometrical method. An idea of it can be gained from his own words at the beginning of his most important work, the *Ethics*. It is the most perfect form of pantheism. Starting from the definition of substance as that which is in itself and is conceived by itself, he shows that there is only one substance—God, the absolutely infinite, with infinite attributes, of which we know only two, thought and extension.

Each of these attributes carries with it an infinity of modes; the totality of these modes is the world. By attribute is meant that which constitutes the essence of substance; by mode, that which is in something else by which also it is conceived. The human soul is only the idea of the human body. The ideas composing it are adequate or inadequate; if the former, it is free and active; if the latter, a slave and passive. True freedom depends upon the extent to which man identifies himself with God by contemplation. *See* *Ethics*; *Metaphysics*; *Pantheism*; *Philosophy*.

Spion Kop, BATTLE OF. Defeat of the British army in the S. African War. Under Buller's plan to relieve Ladysmith by turning the right of the Boer position on the Tugela, Warren crossed at Trichardt's Drift, 5 m. farther up, and essayed a flanking movement.

Warren duly effected his crossing, and on Jan. 22, 1900, decided to attack Spion Kop, an eminence which formed the centre of the Boer right. On the night of Jan. 23-24 the position was captured by the brigade under Woodgate, with whom was associated Thorneycroft in command of mounted infantry. Daybreak showed that the position was very badly exposed. Woodgate was mortally wounded, and the command devolved on Thorneycroft, under whom the position was stubbornly held all day. At nightfall Thorneycroft, regarding the situation as hopeless, decided upon a retreat.

Meanwhile, help was being arranged, and the Boers, discouraged by their failure to regain the summit, had withdrawn their guns from the neighbouring heights. The news, however, reached Thorneycroft too late, and when on the 25th a Boer "forlorn hope" advanced against the summit they found it occupied only by nearly 300 British dead. See South African War.

Spiraea. Large genus of perennial herbs and shrubs of the family Rosaceae, natives of the N. temperate and cold regions. The British species are dropwort and meadow sweet. The name is also used by florists for *Astilbe japonica*. See Meadow Sweet.

Spiral (Lat. *spira*, coil). Curve which runs continuously about a fixed centre with constantly increasing radius vector. The chief spirals are the Archimedean spiral, the radius of which increases uniformly with the angle; the hyperbolic spiral, in which the radius vector is inversely proportional to the angle; and the logarithmic spiral, or spiral of growth as it is sometimes called, the spiral common in nature, e.g. in spiral shells, the angle of which is proportional to the logarithm of the radius vector.

Spire (A.S. *spīr*, a spike or stalk). Acutely pointed structure surmounting a building. The origin of the spire was the steep pyramidal roof characteristic of the secular buildings in France and Germany during the 10th and 11th centuries; when this type of roof was transferred to churches its extension into spire form was begun.

The church of Thaon, Normandy, possessed a rough pyramidal roof dating from the late 11th century, and this has been regarded by

Spion Kop. British troops advancing to the capture of the hill occupied by Boer forces, in the early morning of Jan. 24, 1900

From a drawing by R. Caton Woodville

authorities as the starting point of the spire, and Normandy, especially the Caen neighbourhood, as the scene of its early development.

In England, during the Early English Period (q.v.), when the height of the church towers was greatly increased, spires were raised from the summits, their base being concealed by battlemented parapets and pinnacles. The form of the spire was generally, as in Normandy, octagonal. In this type the spire was a separate structure from the tower, an addition that served merely to finish off the latter; the idea of so blending tower and spire by

means of pinnacles, crotchets, and spire lights as to make one composition of the two, without any assertive line of demarcation between them, was developed on the Continent at a later date. Among the notable spires of Great Britain those of Salisbury and S. Mary's Cathedral, Edinburgh, are respectively highest in England and Scotland. See Autun; Cathedral; Clermont - Ferrand; Norwich; Rouen; Salisbury, etc.

Spires, SPEYER OR **SPIER.** City of Rhineland - Palatinate, W. Germany. It stands on the left bank of the Rhine,

Spies, W. Germany. The Kaiser Halle or vestibule, added to the west end of the Romanesque cathedral, 1854-58

During the Second Great War U.S. 3rd army forces captured Spire, March 23, 1945, against little opposition, German resistance W. of the Rhine having disintegrated. The city came into the French zone of occupation in 1945. Estimated population, 25,000.

Spirit. In theology, the life-giving principle. In accordance with a primitive conception, the word in many languages means the breath (e.g. Heb. *ruach*, Gr. *pneuma*, Lat. *spiritus*, *anima*). God is spirit (John 4, v. 24), but beliefs differ as to the relation of other spirits to God, some regarding them as from their creation eternally distinct, others as emanations from the universal Spirit, into which they will be reabsorbed. The N.T. recognizes impure or evil spirits.

In philosophy, as well as in ordinary speech, the term spirit is commonly equivalent to soul, and is used to denote immaterial, non-extended substance, which feels, wills, and thinks. See Mind; Psychology; Soul.

Spirit of Salt. This chemical preparation is described under Salt, Spirit of.

Spirits. General term for alcoholic liquors above a certain strength. Such liquors include not only those used as drinks, e.g. whisky, brandy, gin, etc., but also those used for lighting, power, and other purposes, e.g. methylated spirit. The word is also used in

chemistry for various solutions, e.g. spirit of hartshorn, a solution of ammonia in water. See Alcohol; Brandy; Distilling; Whisky.

Spiritual. A religious folk song of American negroes. The strong rhythmic quality of spirituals is generally attributed to the negro's African descent, while their subjects point to the Christian teaching he has received since his arrival in N. America. They are mostly on Biblical themes, which are imaginatively treated to make a powerful emotional appeal. Developed in camp meetings on Southern plantations, they are notable for their blend of plaintive melancholy and simple faith; and by their emphasis on the hope of heaven they helped the negro to bear with patience the hardships of slavery.

Spirituals first became widely known in 1871, when a choir of emancipated slaves, calling themselves the Jubilee Singers, left Tennessee on a tour to raise \$20,000 for the funds of their struggling Fisk university. After singing their spirituals in many American cities, they visited England, where they had a sensational success, sang before Queen Victoria, and breakfasted with Gladstone. Their university profited by \$100,000 from this tour. Spirituals gained a vogue on the concert stage in the repertory of professional artists, not altogether to the liking of some negro leaders.

agency), levitation, psychic lights and breezes, materialisations, and psychic photography. Other phenomena, such as raps, table-turning (typology), and direct voice, are physical in operation but mental in content. Physical phenomena occur chiefly at dark séances and their history is clouded with fraud and suspicion; but they have, none the less, been produced under very severe test conditions.

The Basis of Spiritualism

The case for spirit communication rests more upon the evidence of mental phenomena, or rather upon the interpretation of such evidence. The evidence for supernormal acquisition or transmission by a medium of information relating to a deceased person or to circumstances of his life on earth is virtually unchallenged by students of psychical research: such information—often unknown to the sitter, and, more rarely, unknown to any living person, yet verifiable—transmitted by the surviving personality through the medium is the basis of spiritualism. Psychical research, which has been investigating the phenomena for more than 60 years, allows that after eliminating fraud, mal-observation, self-delusion, etc., there are phenomena which have a supernormal (not supernatural) origin; but it offers hypotheses other than that of spirit communication. Some eminent scientific investigators, however, have accepted the spirit hypothesis, notably Sir William Crookes, Sir William Barrett, Alfred Russel Wallace, and Sir Oliver Lodge.

Spiritualism is, to a great extent, organized as a religious community, with churches large and small where services of a simple nonconformist type are held, including a demonstration of mediumship. As a religion spiritualism has no clearly definable doctrine, but expresses itself in a vague theism, with sometimes a leaning towards pantheism. It claims to be a religion based upon facts, but the relation between this theism and the alleged facts of spirit communication is obscure. A large number of spiritualists—though probably a minority—deny that spiritualism is a religion in itself, and insist that its claims can be accepted without loss of loyalty to one's existing faith. Among these are many Christian ministers. Religious spiritualism in the U.K. is represented by two major organizations of affiliated churches, the Spiritualists' National Union and the Greater World

SPIRITUALISM AND ITS CLAIMS

H. J. D. Murton, Editor of *Light*

In this article the editor of a well-known Spiritualist periodical tells the history and explains the central beliefs of Spiritualists. See Home, D. D.; Medium; Planchette; Psychical Research; Survival; Telepathy

In the widest sense of the term Spiritualism means any system of thought opposed to materialism. It is, however, generally used in reference to the belief that, in certain conditions, it is possible for communication to take place between the living and the dead. What are called psychic phenomena have occurred all down the ages, and the Bible is rich in incidents and manifestations which can, it is claimed, be interpreted as being of a similar nature to phenomena occurring today. Spiritualism, however, is regarded by its adherents as having originated in 1848 at Hydesville, in the state of New York, U.S.A., when certain rappings, occurring in the home of the Fox family, were traced, it is alleged, to a discarnate source, a code being arranged by which the purporting communicator could

answer questions and spell out messages by the raps. The three Fox sisters became practising mediums, and the movement spread rapidly through the U.S.A.

In 1852 American mediums visited England, but met with little success until the arrival of D. D. Home. The movement spread to the Continent, and in France, under the influence of alleged spirit teachings received by Allen Kardec, it adopted reincarnation as one of its beliefs; a belief held by a large and possibly growing number of English spiritualists.

The phenomena of spiritualism are divided into two classes, mental and physical. Mental phenomena include clairvoyance, clairaudience, trance utterances, and automatic writing. The physical phenomena are telekinesis (movement of objects without known

Christian Spiritualist League. The other kind of spiritualism is represented by independent societies such as the London Spiritualist Alliance, with its organ *Light*.

Generally speaking, the Church is hostile towards spiritualism, the R.C. Church uncompromisingly so. In 1938 Dr. Lang, then archbishop of Canterbury, received a report from a committee he had appointed about four years earlier, of prominent clergymen and laymen, to inquire into spiritualism. This report, which represented the majority view of the committee, the archbishop declined to publish, but it was subsequently published by a spiritualist weekly newspaper, *Psychic News*. It stated that, while the strictly scientific verdict on the matter of personal survival was not proven, certain psychic experiences made a *prima facie* case for survival, and when every possible explanation of alleged spirit communications has been given and all doubtful evidence set aside, it was probable that the hypothesis that they proceed in some cases from discarnate spirits was the true one.

While there is undoubtedly a strong non-Christian, and to some extent anti-Christian, element in spiritualism, it is claimed that the evidence for human survival endorses a basic article of Christian faith. On the other hand, spiritualists often assert that survival is thus shown to be a natural, not a supernatural, fact; a biological rather than a religious matter. They argue, however, that knowledge of a life beyond death is an essential factor in the full understanding of man's purpose in life and of the moral obligations involved. The signatories of the majority report mentioned allow that if spiritualism contains a truth, it fills up certain gaps in human knowledge, but they also issue a warning that "it is not legitimate, and it is unquestionably dangerous, to allow an interest in spiritualism, at a low level of spiritual value, to replace that deeper religion which rests fundamentally upon the right relation of the soul to God Himself."

The general position, stated without bias, seems to be that evidence pointing to spirit communication undoubtedly exists. It is not strictly scientific, but more in the nature of "legal" evidence upon which the verdict must be a matter of personal judgement. To spiritualists the verdict is proven; to non-spiritualists it is either non-proven or no case.

Spiritualities (Lat. *spiritualia*). Ecclesiastical term for the power bestowed upon a bishop at his consecration and confirmation, and for the ecclesiastical revenue arising from other sources than land. The temporalities consist of the endowment of a see. See Ecclesiastical Law.

Spirit-Worship. Ritual homage offered to incorporeal beings or powers conceived as dwelling in visible objects or in the invisible world. In its stricter sense the term denotes the veneration of, or appeal through offering and prayer to, friendly agencies below the rank of deities. In common usage it embraces also the propitiation of evil spirits or hostile demons under the impulse of fear. See Ancestor-worship; Animism; Demonology; Fetishism; Mana.

Spit. Long narrow bank of sand or shingle connected at one end to the shore. Spits often continue the general trend of the shore line, though they may grow out across the inner part of an inlet. By continuation of growth a spit may develop into a bar across the mouth of a bay, and so impound a lagoon, which will gradually silt up. Spits grow according to the supply of material transported along the shore by wave action; but at the free end the material is carried past the line of the spit and deposited behind it. This leads to the development of a hooked spit. See Coast.

Spitalfields. Dist. of E. London. In the met. bor. of Stepney (*q.v.*), it lies between Whitechapel and Mile End New Town, E., and the City and Shoreditch, W. Christ Church, by Hawksmoor, opened 1728, and several times restored, is notable for its arched portico and clock tower, and has an outdoor pulpit.

In Roman times a burial ground, and once known as Lolesworth,

Spitalfields was named later after fields adjoining the priory and hospital of S. Mary Spital, founded 1197. The silk industry was established here by French Huguenot refugees in 1685 and flourished for a century or more. Spitalfields Market for fruit and vegetables dates from the 17th century. In 1928 a new market was built by the corporation at a cost of £2,000,000; it covers six acres, has a mile and a half of warehouses and stands, and an open auction sale-room.

Spitfire. British fighter aircraft. Designed by R. J. Mitchell (*q.v.*), and built by Vickers-Armstrong Supermarine works, the Spitfire was based on the seaplanes which won the Schneider Trophy (*q.v.*) in 1927, 1929, and 1931. The first military version flew in 1936, and delivery to squadrons of the R.A.F. began in 1938. At the outbreak of the Second Great War the Spitfire and Hurricane (*q.v.*) equipped almost all the home defence fighter squadrons and played an outstanding part in the battle of Britain. When the Allies assumed the offensive in N. Africa, Burma, and Europe, the Spitfire was adapted to a variety of rôles: all-altitudes fighter; escort; fighter-bomber; photographic reconnaissance craft; and naval fighter (Seafire). Originally powered by a 1,030 h.p. Rolls-Royce "Merlin" engine giving a max. speed of 342 m.p.h., the Spitfire progressively advanced in speed to the 450 m.p.h. of the Mark 24, powered by a 2,035 h.p. Griffon engine, introduced in 1946. Armament increased in hitting power from the eight Browning .303 machine-guns in 1938 to four 20 mm. cannon in 1946. The standard wing span was 36 ft. 10 ins., but there were several variations in wing design. During the war Spitfire funds were opened to help provide the aircraft for the R.A.F. and found generous response. After the war the Spitfire was gradually withdrawn from the first line. A later development, the Spitfire (with naval version, Seafang) never went into service. See Aeroplane illus. p. 129; Britain. Battle of.

Spithead. Roadstead off the S. coast of England. It extends for 12 m. N.W. to S.E., between East Cowes and Portsmouth, has an average breadth of 4 m., and communicates with the Solent and Southampton Water on the W. See Portsmouth.

Spitsbergen OR SVALBARD. Arctic archipelago. Lying 360 m.

Spitsbergen. Map of the Arctic archipelago lying to the north of the Norwegian coast

N. of Norway, which annexed it in 1925, and extending from lat. $76^{\circ} 25' N.$ to $80^{\circ} 50' N.$, and from long. $10^{\circ} 30' E.$ to $36^{\circ} E.$, it consists of the mainland or West Spitsbergen; North East Land, King Karl Land, Barents, Edge, and Hope Islands on the E.; Prince Charles Foreland on the W.; and many smaller islands. Bear Island, 130 m. S.S.E. of Spitsbergen, is generally included in the archipelago. The total land area of the group is about 24,294 sq. m.

The whole country is mountainous, rising to peaks of about 3,000 ft., exceeding 5,000 ft. in the N.E. The main island is deeply dissected on the W. and N. by long branching fjords which give deep water access to the heart of the country. Of these Ice Fjord, 56 m. long, is the most important. Good natural harbours are numerous.

The country is heavily glaciated, but with the exception of North East Land, which is practically covered by an ice-cap, and New Friesland in the N.E. of the mainland, there is no inland ice in the sense in which the term is used of Greenland and Antarctica. The ice takes the form of long, much crevassed glaciers each confined to its own valley; most glaciers reach the sea. The winter is severe, but July to Sept. give temperatures well above freezing.

Vegetation is scanty, but there are patches of luxuriant tundra in places. Bird life is abundant in summer. Land animals include the reindeer, fox, and polar bears. Various whales and seals occur. Since its discovery by the Dutch in 1596, Spitsbergen has been the resort of whalers, trappers, and hunters. Since about 1900 the minerals found have included coal, copper, and asbestos.

A treaty signed in Paris, Feb. 9, 1920, placed Spitsbergen under Norwegian sovereignty, and on Aug. 14, 1925, that country formally took possession of the archipelago. During the Second Great War a raid was made in 1941 by Canadian, British, and Norwegian forces to forestall a German plan to seize the rich coal mines on Spitsbergen. The Allies brought the 700 miners and their families to Great Britain and destroyed the mines. British and German meteorologists collected data in the fjords until the Germans were forced to leave. On Sept. 8, 1943, German naval forces, including the warships Tirpitz and Scharnhorst, made an attack on the archipelago. In 1947 the U.S.S.R. approached Norway regarding military bases on Spitsbergen, and the Norwegian garrison was withdrawn.

Spitteler, CARL (1845-1924). Swiss poet and philosopher, born April 24, 1845, at Liestal. After

Spleen. Front and side view of the abdominal organ

studying law and theology, he taught in Russian and Finnish families during 1871-79, while preparing his first great work, Prometheus and Epimetheus, a parable. Published under the pseudonym C. F. Tandem, 1881, it remained long unnoticed, while Spitteler returned to Switzerland. He published poetry, allegory, essays, a 4-vol. poetic work, Olympian Spring (1900-06), and a novel Imago (1906). Another Prometheus volume followed in 1924. Sometimes compared to Nietzsche in his sorrowing but defiant attitude to life, Spitteler was fundamentally a healthy personality whose idealism gained strong influence over the German-speaking world. Among many honours he received the Nobel prize for literature, 1919. He died in Lucerne, Dec. 29, 1924.

Splay (abbrev. of display). In building and joinery, a surface making an oblique angle with another surface. The jambs of windows are splayed in order to admit more light. The term is applicable to surfaces larger than a chamfer (*q.v.*) or bevel.

Spleen. Organ of oblong, flattened form placed in the upper part of the abdomen on the left side. It is about 6 ins. long, 3 ins. broad, and weighs from 6 to 8 ounces. The spleen is the largest of the ductless glands. Its functions are (1) to form white blood corpuscles and, in certain animals, red corpuscles; (2) to disintegrate some of the red blood corpuscles which have discharged their function and are worn out; (3) to take part in nitrogenous metabolism by the formation of uric acid.

DISEASES OF THE SPLEEN. Enlargement of the spleen is a symptom of many diseases, including malaria, leucocythemia, Hodgkin's disease; it may also occur in congenital syphilis and rickets. Splenomegaly, or splenic anaemia, or Banti's disease, is a disorder in which enlargement of the spleen is associated with increasing anaemia. Haemorrhage is often a serious symptom. The disease is chronic and may last 10 or 12 years. Removal of the spleen has been followed by cure, but the operation is serious, and should be undertaken only in severe cases.

Spleenwort (*Ceterach officinarum*). Fern of the family Polypodiaceae. It is a native of Europe, W. Asia, and N. and S. Africa: common in many parts of Britain.

Spleenwort. Scaly spleenwort. *Ceterach officinarum*, that grows on rocks and masonry

The fronds grow in a tuft from rocks and masonry, each being narrow-lance-shaped, the two sides cut into semi-elliptic lobes. They are of leathery consistency, the upper side green and smooth, the underside shaggy with long chaffy scales, which are silvery on the young frond, red-brown on the mature. The fern curls up and looks withered in dry weather, but expands again in moisture. Its other names are rusty-back, scale-fern, finger-fern, and milt-waste.

The ceterach is the plant referred to as spleenwort in all the old herbals and medico-botanical works; but in modern times spleenwort has been adopted as a popular name for all the ferns of the extensive genus *Asplenium*, of which there are about 300 species, nine of them natives of the U.K. These include the wall rue (*A. ruta-muraria*), maidenhair spleenwort (*A. trichomanes*), black spleenwort (*A. adiantum-nigrum*), and sea spleenwort (*A. marinum*). All grow naturally in rock crevices, but several take possession of decaying masonry, a trait which indicates their special suitability for cultivation in the rock garden, where they should be given a rather elevated and well drained position. See Fern.

Splice. Term used for the joining together of two ends of rope. It is done by untwisting their strands for a short distance and threading the strands of each rope under and over those of the other in such a manner that a joint is formed by the friction of the strands on one another. Where it is desired to avoid increasing the thickness of the rope at the joint,

the loose ends of the strands are cut to varying lengths and thinned down to points. The strands of one rope are then twisted into the vacant spaces in the other rope,

Splice. Stages in making common forms of splice. Top, short splice, joining two rope ends; below, eye splice, for making a loop

Split, Yugoslavia. The quayside of this seaport on the Dalmatian coast

and the tapered ends threaded as above described.

The term also means to unite two pieces of wood by tapering the ends so that they overlap, gluing them together, and sometimes binding them. In another form of splice, one end is tapered centrally and fits into a corresponding tapered recess in the other piece. These forms of splice are used for golf clubs, cricket bats, and other implements of sport. In carpentry and engineering, a method of joining the ends of two pieces of timber or metal by means of side strips or plates bolted or riveted to the main pieces is known as splicing. See Ship.

Splint. Artificial support for limbs when the bones are broken, or weakened or bent by disease. Splints may be made of wood, leather, zinc, poroplastic material, etc., and are of numerous forms, sizes, and shapes, according to the condition of the limb or the purpose to be achieved. Splints of poroplastic or leather have the advantage that they can be softened and moulded to the form of the limb. See First Aid.

Splint. Bony enlargement on the shank bone of a horse. It is extremely common, more frequently in the fore than the hind legs, and on the inside rather than the outside. Slight cases give little trouble, but lameness may be caused in young horses.

Split. Seaport and town of Yugoslavia, in Dalmatia. Known to the ancients as Aspalathos, and to Italians today as Spalato, it stands on a peninsula on the Adriatic Sea, picturesquely encircled by hills, 74 m. S.E. of Zara (Zadar), and is a rly. terminus. The dominating building is Diocletian's palace, put up when that emperor founded the town in 303. His mausoleum was transformed

into a cathedral, '650, dedicated to the Virgin, and has reliefs on the portal depicting scenes in the life of Christ. Wine, oil, wheat, figs, and leather are the principal products of Split, which has also fisheries. Upon the surrender of Yugoslavia to Germany in 1941, the town was garrisoned by Italians. These became disaffected and in Sept., 1943, combined with Marshal Tito's partisan forces to hold the port for a fortnight against German bombing attacks. Patriots finally liberated it, after three days' fighting, on Oct. 29, 1944. Pop. 43,711.

Split Infinitive. The infinitive form of a verb in English involves the use of the word *to*. Thus, *to state* is an infinitive; to interpose an adverb thus, *to openly state*, is to split the infinitive. This practice is reprehended by grammarians and most stylists, the accepted form being *to state openly*, or *openly to state*. To split an infinitive is preferable, however, if avoiding it would cause ambiguity.

Splügen. Alpine pass between Switzerland and Italy. Its height is 6,945 ft. There is a carriage road between Chiavenna and Coire (Chur), connecting the valley of the farther or hinter Rhine with that of Lake Como. The road over the pass was constructed by the Austrian government, 1819-21, and has three galleries as a protection against avalanches on the Italian side. A French army crossed the pass in 1800.

Spode. Variety of chinaware. In 1770 Josiah Spode began to make feldspar porcelain at Stoke-upon-Trent. He introduced crushed bone into its composition, which was a soft paste, giving a very transparent body. Spode's shapes were good, and his pieces rather highly decorated with flowers and gilding. He was succeeded by his

Spode Porcelain. Plates of the delicate decorated chinaware made by Josiah Spode
Herbert Allen Collection, Victoria and Albert Museum

son, and the firm became one of the leading houses in the trade. See Pottery.

Spodumene (Gr. *spoldos*, ashes). In mineralogy, a lithium and aluminium silicate. It has a grey, green, yellow, or purple glassy lustre and is found in granite pegmatites. The biggest deposits of this important ore mineral are in Dakota, U.S.A. Two varieties, hiddenite and kunzite, in colour respectively emerald green and lilac, are out as gemstones.

Spofforth, FREDERICK ROBERT (1853-1926). Anglo-Australian cricketer. Born at Balmain, Sydney, Sept. 9,

F. R. Spofforth,
Anglo-Australian
cricketer

1853, he played for New South Wales and Victoria, and on settling in England qualified for Derbyshire. He was a member of the first Australian team to come to England in

1878, and during the tour took 352 wickets. His most remarkable performance was capturing 11 wickets for 20 runs against a strong M.C.C. eleven. In 1884, his greatest season with the ball, he took 218 wickets in first-class cricket for an average of 12.53 runs. In test matches he captured 94 wickets for 1,731 runs, and performed the hat-trick in the match at Melbourne in 1879. Perhaps the greatest who ever lived, the "demon bowler" died June 4, 1926.

Spohr, LOUIS OR LUDWIG (1784-1859). German composer. Born at Brunswick,

April 5, 1784, he showed precocious musical talent and entered the court orchestra at Brunswick in 1798. An able violinist, he wrote

Louis Spohr,
German composer

of the earlier Romantic school, Spohr wrote some 200 works, including eleven operas, several oratorios, notably *The Last Judgment*, 1826, nine symphonies, and chamber music. His violin concertos are perhaps his most memorable works, and he had great influence in developing the technique of that instrument. His violin course, still a standard work, was published in 1831, and his autobiography, 1860, Eng. trans. 1865.

Spokane. City of Washington, U.S.A., the co. seat of Spokane co. It stands on the river of the same

his first violin concerto in 1802. He toured extensively in Germany, visited England in 1820, conducting Philharmonic Society concerts with success, and was court conductor at Cassel during 1822-57. He died there on Oct. 22, 1859. A leading composer

of foundry and machine-shop products, bricks, furniture, flour, pottery, and brooms. The celebrated Spokane Fall is within the city, and generates water power. Just outside is Fort Wright, an army post. The pop., which trebled between 1900 and 1910, is 122,001.

Spoleto. City of Italy, in the prov. of Perugia. It occupies the centre of an agricultural dist., and crowns a hill about 1,470 ft. in elevation, 88 m. by rly. and 61 m. direct N.N.E. of Rome. Lucrezia Borgia was imprisoned in 1499 in the citadel which dominates the town. A Roman bridge and aqueduct spans the ravine between the main height and Monte Luco; many other Roman remains exist. The 11th century cathedral of S. Maria Assunta has a later Renaissance portico; several churches occupy the sites of Roman temples. That of S. Salvatore was partly unroofed in the Second Great War. The chief occupations are gathering truffles, meat preserving, and the manufacture of olive oil and silk. The ancient Umbrian town, Spoletum, became Roman in 241

Spoleto, Italy. The hilltop citadel that dominates the city, and the Roman bridge and aqueduct

name, 340 m. by rly. E. of Seattle. It is the seat of Gonzaga and Spokane universities, and Whitworth and Spokane colleges. From 1810 a Canadian fur trading outpost, with the discovery of gold in the neighbourhood it was transformed into a teeming town in the 1870s. The city charter dates from 1881. There are valuable lumber interests, and in the surrounding districts gold, silver, copper, and other minerals are mined. Other occupations include wheat and fruit growing, and the manu-

b.c., was destroyed by the Goths, rebuilt by Narses, and became the capital of the Lombard duchy of Spoleto. It was a Papal possession from 1220 to 1860.

Spoleto, ALMONTE, DUKE OF (b. 1900). Italian nobleman. Son of the duke of Aosta, he was a cousin of ex-King Victor Emmanuel III. He was proclaimed King Tomislav of Croatia, 1941, after the German conquest of Yugoslavia, but never assumed the throne and renounced it in 1943. He succeeded his brother as 3rd duke of Aosta, 1942.

Sponge. 1-8. Spicules: 1, 6-ray type, with distal ray suppressed; 2, 4-ray; 3 and 5, 6-ray, with secondary rays; 4, bow-shaped, with modified ends; 6, needle-shaped; 7, irregular rays, with branched ends; 8, star-shaped. 9. Ectoderm and, top, endodermic cells, magnified 500 times. 10. Calcareous sponge, with well-defined spicules. 11. Venus flower-basket. 12. Turkey sponge, and (right) hard sponge

Spondee. In prosody, a foot containing two long, or accented, syllables. The word is derived from the Gr. *spondē*, a libation, because this slow, dignified measure was much used in the hymns sung at solemn libations.

Sponge. Name given generally to the lowly animals of the subkingdom Parazoa, phylum Porifera. Most of them occur in stocks or colonies, but some are simple indi-

viduals. A simple sponge consists of a short tube, attached at the base to some object and with an opening at the top, the osculum. The body wall is pierced by numerous pores through which water enters the internal cavity, and is then expelled through the osculum. By this means minute particles of food are introduced to the body. There is an intermediate layer or layers of jelly and cells between the inner and outer integuments, called the endoderm and the ectoderm. There are no internal organs, but part of the body cavity

is lined with specialised cells, called choanocytes (funnel-vases), which catch and absorb the minute organisms on which the animal feeds. Other cells are specialised for the reproductive functions; and still others secrete the minute flinty or calcareous spicules which strengthen the body wall and form a loose skeleton.

The majority of sponges are branched and complicated; and

some of them secrete a horny skeleton instead of spicules. It is these horny skeletons, cleansed from the soft animal matter, which form the sponges of commerce. Reproduction in the sponges takes place very variously. Fission, budding, and sexual propagation all occur in different species.

Sponges assume the most varied forms, and many of the flinty ones—e.g. the Venus flower-basket—are very beautiful. Those that occur around the British coasts are small and inconspicuous; but in the tropical and sub-tropical seas they grow to a great size. Of the horny sponges, the Turkey cup sponges are of the finest texture and are in great demand for toilet purposes.

The sponge "fishery" is carried on by trawling and the use of long pronged forks; but the best species are always obtained by diving. See Animal, colour plate; Crab; Germination; consult also Monograph of the British Spongidae, J. S. Bowerbank, 1882; Porifera, I. B. J. Sollas, 1909; Freshwater Sponges, N. Annandale, 1911; Sponges, E. J. J. Creswell, 1921.

Sponsor (Lat. *spondere*, to promise). Name given to one who, at Christian baptism, promises, in the name of the baptized, to keep the faith. See Baptism; Godfather.

Spontaneous Combustion. The burning of a substance by heat generated within itself. Generally it is due to heat developed by rapid oxidation, a form of violent chemical action. Oil distributed on cotton waste frequently causes fires by spontaneous combustion. Coal, freshly mined, sometimes burns spontaneously, the cause being the oxidation of the paraffin hydrocarbons on exposure to air.

The now discredited theory that spontaneous combustion is possible in human beings of marked alcoholic tendencies has been employed in fiction. An instance is the fate of old Krook in Dickens's *Bleak House*. See Pyrophorus.

Spontaneous Generation. The doctrine which puts forward a view that living matter can come into existence from non-living material. In the absence of any satisfactory evidence in its favour, the doctrine is rejected by most modern biologists. See Abiogenesis; Biology; Life.

Spoon. 1. Pewter, 15th-16th century. 2. Horn, 16th-17th cent. 3 and 5. Latten, tinned, 17th cent. 4. Pewter, 17th cent. 6. Pewter, 18th cent. Guildhall Museum, London

Spoon (A.S. *spon*, a chip of wood). Implement consisting of a small bowl with a handle, used primarily for conveying liquid or soft food to the mouth. The ancient Egyptians made spoons of ivory, flint, etc. Greek and Roman spoons were of metal, the handle often ending in a point for extracting snails from their shells.

In England the cheaper metals, such as pewter, began to supersede wood and horn as the material of spoons towards the close of the Middle Ages, but silver spoons were long a rarity. The form and decoration varied until the latter part of the 18th century, when the style approximated to that now in use. See Apostle Spoon.

Spoonbill (*Platalea leucorodia*). Bird, related to the ibis, and distinguished by its long flat beak, which widens out at the tip somewhat like a spoon. It is about 32 ins. long, and has white plumage with a tinge of buff on the neck. The beak is black with the exception of the tip, which is yellow. The legs are long, and the general form of the bird is suggestive of a heron. It is common throughout central and S. Asia and Europe, and formerly bred in Great Britain, where it now occurs as a visitor to Norfolk. It is always found near water, usually in marshes, and feeds upon small molluscs, crustaceans, frogs, and fish.

Spooner, WILLIAM ARCHIBALD (1844-1930). An English scholar. Born July 22, 1844, he was educated at Oswestry and New College, Oxford. Ordained in 1872, he became chaplain to Archbishop Tait in 1878, and was warden of New College, 1903-1924. His works included an annotated edition of Tacitus, 1891; Life of Bishop

Butler, 1901; Memoir of William of Wykeham, 1909. He died Aug. 29, 1930. See Spoonerism.

Spooner, WINIFRED (1900-33). English airwoman. In 1928 she was the first woman to compete in the king's cup air race round Great Britain, and led as far as Newcastle, but finished third. In 1930, making an attempt with a companion on the England-to-Cape record, she crashed in the Tyrrhenian Sea and swam two miles to land. That year she was acclaimed world champion woman aviator and awarded a trophy by the international league of aviators. She died of influenza, Jan. 13, 1933.

Spoonerism. Confused expression of an amusing nature. The term is derived from the habit of Dr. W. A. Spooner (*q.v.*) of accidentally interchanging sounds, usually the initial ones, in words in close association. A genuine spoonerism was, "I believe you are occupewing my pie" for "I believe you are occupying my pew."

Sporades (Gr. *sporadikos*, scattered). Name of a group of islands in the Aegean Sea, since 1948 part of the kingdom of Greece. They are alternatively known as the Dodecanese, and are so described in this Encyclopedia. The N. Sporades are another group lying off Euboea, the largest island being Seyrus (*q.v.*), and others Skiatho, Skopelo, Cheliodromia, and Pelago. All are rocky and wooded. Sponge fishing is the chief occupation of the inhabitants.

Spore (Gr. *sporos*, seed). Reproductive cell of plants. Reproduction by spores is one of the most prominent means of plant growth, and may be asexual or sexual. The spores of many plants, *e.g.* fungi, are light and easily carried through the air by the wind, while others are so constructed as to cling to passing animals, etc. Most consist of a hard outer and a

delicate inner wall, and receive names according to their type, *e.g.* the basidiospores of toadstools, and vary considerably in their external structure. Sexual spores are the result of the fusion of two sexual cells or gametes. Zygospores are the result of the union of similar gametes, and oöspores the union of dissimilar gametes. See Cell; Meniscium; Moss; Oleandra; Pillwort; Pteris; Seed.

Sporozoa (Gr. *sporos*, seed; *zōon*, animal). Parasitic protozoa. So called from reproducing by means of spores, sporozoa form important and widespread organisms, and include malaria germs, Texas cattle-fever germs, tsetse disease, etc. Living by absorption of the fluid juices of the tissues of their host, sporozoa develop from spores which break up into small bodies or sporozoites, and before their life cycle is complete they must leave their original host for a second host.

Thus the sporozoites of malaria are developed in mosquitoes and are then transferred to man. Usually the two hosts are one vertebrate and the other an invertebrate. Nearly all sporozoa are microscopic, and the methods of destroying them are prevention of their transference from one host to another, or killing the original host. Mosquito nets provide an example of the first method, and the proper drainage of stagnant pools and destruction of the breeding-grounds of the insect exemplify the second. See Malaria; Parasite.

Sporran (Gael., purse). Purse or pouch of leather worn in front of the kilt by Scottish Highlanders. It is usually made of fur. See Highlands.

Sporting Gun. Term in general use to define a firearm which discharges small shot for killing small game. All modern sporting guns are breech loading and employ central fire cartridges. See Gun.

Sporting Times, THE. London weekly newspaper which appeared from 1865 to 1932. Dr. Shorthouse and John Corlett started it, the latter being proprietor and editor, 1874-1912. The "Pink 'Un," named from the tint of its paper, specialised in horse racing and the music hall, and also invented the term Ashes (*q.v.*) in connexion with Anglo-Australian cricket.

Spotted Fever. Popular name for the infectious disease cerebrospinal fever (*q.v.*).

Spottiswoode. Scottish family. It is traced back to a Robert Spottiswoode who held a barony of this name in Berwickshire in the time of

Spoonbill. Flat-beaked marsh bird, related to the ibis

Alexander III (1241-86). A cadet was lieutenant-governor of the colony of Virginia. In 1819 Andrew and Robert Spottiswoode succeeded their uncle, Andrew Strahan (d. 1831), in the management of the London printing business founded by Charles Eyre and William Strahan (1715-85) and a share in the king's patent.

The death of his brother in 1832 left Andrew in sole control of the business. He resigned his share in the royal patent to his elder son, William (1825-83), who thus became partner in the firm of Eyre and Spottiswoode. William, a distinguished mathematician and physicist, was P.R.S. from 1878 until his death, June 27, 1883.

Sprain OR **Strain**. Tearing or stretching of the synovial membrane of a joint or of ligaments, resulting from sudden violence applied to the joint. Inflammatory effusion, swelling, and pain follow. Immediately after the accident, the joint should be supported with a firm, wet bandage, and the limb kept quiet and raised. An evaporating lotion should be applied to the bandage from time to time. Gentle movements of the joint should be made after the acute symptoms have subsided, followed, as the swelling decreases, by massage and exercises of the joint. *See* First Aid; Massage.

Sprat. Small variety of herring caught off the British coasts

Sprat (*Clupea sprattus*). Small European fish of the herring family, common in British seas. It varies in length from 3 to 5 ins. when adult, the young figuring largely as whitebait. Its chief distinction from the herring, apart from its small size, lies in the absence of teeth from the vomerine bone. Sprats occur in brackish water about river estuaries; but spawning takes place at sea. The fishery is of importance in the late autumn, seines, drift nets, and stow nets being used.

Spree. River of Germany. It rises in Saxony near the border of Czecho-Slovakia, and flows generally N.W. to join the Havel at Spandau, after a course of 226 m. The lower course has been deepened to allow large vessels to reach Berlin. Canal connexions provide access to the Oder and navigation to Stettin.

Sprengel Pump. Pump for obtaining high vacua. Invented

by the German chemist H. J. P. Sprengel, it consists essentially of a vertical capillary glass tube, its upper end communicating with a funnel by means of an indiarubber tube which can be compressed as required. Below the indiarubber connexion is a lateral branch of the glass tube to the vessel in which a vacuum is desired. The lower end of the tube is bent and dips into a trough. The funnel is filled with mercury, which is allowed to drip past the lateral connexion, and in doing so traps a portion of the air from the vessel and carries it down the tube. The continued application of the method finally exhausts the air from the vessel. *See* Pump.

Spring. First season of the year. In the N. hemisphere it is reckoned astronomically from the vernal equinox (about March 21) to the summer solstice (about June 21). In the S. hemisphere it corresponds in date with the N. autumn. *See* Seasons.

Spring. Natural outflow of underground water. When rain falls, some of it remains in pools upon the surface and is quickly evaporated, some runs off the surface to join a rivulet or stream, some sinks into the soil and is used by plants, whilst if the rock below the soil is permeable, some finds its way to a greater depth, where it reaches the surface below which the rocks are saturated with water. The top of this saturated zone is termed the water table.

The level of the water table varies with the kind of rock, rainfall, and topography. Where valleys cut down to the water table, water will flow out on the surface of the land and valley-springs are formed (*see* Diagram 1, V-Sp). In wet weather the water table rises, and if it then reaches the level of a valley floor a seasonal spring or bourne is produced (*see* Diagram 2, b). Stratum-springs result from the underlying of a porous bed by an impervious one, and the junction of the two outcropping on a hillside. The lower impervious bed checks the normal downward pas-

sage of water, and the flow is deflected along the junction surface to escape at the lowest point (*see* Diagram 3, S-Sp). Springs often occur also along faults (Diagram 4, F-Sp), which are planes of shattering in the earth's crust. Such springs are a type of artesian spring which results from underground water in a porous horizon managing to break or force a passage upwards by pressure through overlying impervious strata. Hot springs are found either in areas of recent volcanic activity or where water is rising to the surface from considerable depths in the crust. *See* Fault; Well-sinking.

Spring. Elastic body of metal, rubber, wood, or enclosed fluid, to exert, resist, or store up force. The most common forms of metal springs are here illustrated. The spiral spring is used chiefly for

Spring. Principal types of mechanical spring. 1. Torsional. 2. Spiral. 3. Helical. 4. Double spiral. 5. Cantilever (laminated). 6. Semi-elliptic (laminated).

clockwork, and is subjected to bending. Helical compression and tension springs are designed to resist compression and extension in the direction of their axes. The primary stresses in the material are torsional. The stiffness of both these types varies as the fourth power of the diameter of the wire, other things being equal. They may also be used to transmit force circumferentially, *e.g.* the springs of a mouse-trap.

The laminated spring is that most generally employed for vehicles of all kinds. It is composed of a number of steel plates bound together at the centre or at one end, but free to slide over one another at other points. The length of the

Spring. Diagrams showing types of natural springs. 1. Valley spring. 2. Bourne. 3. Stratum spring. 4. Fault spring.

plates increases regularly to give the spring the shape of a triangle, or two triangles set base to base. The plates are curved, so that they will be straightened by the greatest load they are called upon to carry. It is important that all the plates should be of the same width and thickness. The elasticity of a spring varies inversely as the cube of the thickness, other factors being equal.

Buffer springs for rly. rolling-stock may be large disks of rubber, 2 ins. thick, separated by metal plates.

Air under compression is the most perfect form of spring, as it is infinitely elastic and has no limit of strength.

Spring, HOWARD (b. 1889). British novelist. Born in Cardiff Feb. 10, 1889, one of a family of nine, he lost his father when he was eleven. Leaving school at 12 to start work as a messenger boy, he later became a reporter on the South Wales Daily News, which he left in

Howard Spring,
British novelist

1911 to join the Yorkshire Observer. At the outbreak of the First Great War he was on the staff of the Manchester Guardian, to which he returned after serving in the Intelligence branch, G.H.Q., France. His life in Manchester clearly had great influence on him, as he made it the scene of several novels. In 1931 he joined the London Evening Standard, of which he became book critic. His first story, Darkie and Co., 1932, was written for his children, and after two novels, The Shabby Tiger, 1935, and Rachel Rosing, 1936, he wrote two more children's books, Sampson's Circus and Tumbledown Dick, 1936. O Absalom (repub. as My Son, My Son), which appeared in 1938, was translated into most European languages. Like his Fame Is the Spur, which followed, 1940, it was filmed. Of his later books, Hard Facts, 1944; Dunkerleys, 1946; and There Is No Armour, 1948, are novels, while Heaven Lies About Us, 1939; In the Meantime, 1942; and Another Thing, 1946, are all autobiographical.

Springbok (*Gazella euchore*). Species of gazelle found in S. Africa. It stands about 30 ins. high, and has cinnamon-yellow hair with white under parts and a line of

white hair along the back. The horns are lyre-shaped and about 15 ins. long, and they are present in both sexes. The animal is noted for its high bounds when running.

The name Springboks has been popularly used for teams of S. African cricketers or Rugby football players in the U.K., also for S. African troops.

Springfield. City of Illinois, U.S.A., the state capital and the co. seat of Sangamon co. It is 186 m. S.W. of Chicago, and is served by the Illinois Central and other rlys. Manufactures include watches, lumber products, woollen goods, flour, engines, boilers, soap, and bricks. Farming and horse-breeding are important local industries. Some 20 coal mines are in the vicinity. In this city (incorporated 1832, becoming a city 1840) Abraham Lincoln practised law for the quarter-century preceding his presidency. He is buried in the crypt of the national monument erected to his memory in Oak Ridge cemetery. Pop. 71,864.

Springfield. City of Massachusetts, U.S.A., co. seat of Hampden co. It stands on the Connecticut river, 100 m. by rly. W. by S. of Boston, and is served by the Boston and Maine and other rlys. Educational institutions include the American International College and the Y.M.C.A. College. The park system covers 1,600 acres. Industries include the manufacture of electric cars, motor vehicles, cotton and woollen goods, electrical appliances, cigars and tobacco, machinery, and confectionery. Settled in 1636, Springfield was chartered as a city in 1852. Here John Brown, in 1847-49, organized a post to enable runaway slaves to flee to Canada. In 1927 the rising river flooded low-lying portions, causing property losses amounting to millions of dollars. Pop. 149,554.

Springfield. City of Missouri, U.S.A., the co. seat of Greene co. It is 225 m. by rly. W. by S. of St. Louis, in the Ozark Mts., and is served by the St. Louis and San Francisco rly. Native Missourians form 73 p.c. of the pop., and one-fifth of the workers are employed by the railroads, most of the rest by processing the output of farms lying within a 150-m. radius. Springfield was settled in 1830.

Springbok. South African
species of gazelle

incorporated in 1838, and became a city in 1881. Pop. 61,238.

Springfield. City of Ohio, U.S.A., the co. seat of Clark co. It stands on Mad river, at its confluence with Lagonda Creek, 44 m. W. of Columbus, and is served by the Cleveland, Cincinnati, Chicago and St. Louis, and other rlys. Witten-

berg College (Lutheran) is here. Motor truck manufacture and the printing of four national magazines are important industries. About five million rose plants are sent out annually from the city's many greenhouses. First settled in 1799, Springfield was incorporated in 1827, and became a city in 1850. Pop. 70,662.

Spring-gun. Mechanical arrangement in which a trip wire is fastened to the trigger of a gun or rifle in such a way that anyone pulling the wire discharges the gun. To set one in a way which may cause bodily harm is illegal. Spring-guns were formerly used to a considerable extent to prevent poaching on game preserves, and they are frequently employed in military defence work.

Springhill. Town of Canada, in Nova Scotia. It is 75 m. due N.N.W. of Halifax, and is the centre of a colliery dist. served by the Cumberland rly. and Coal Company rly. Pop. 7,170.

Springtail. Order (Collembola) of small wingless insects, which have

Springtail. Orchesella
cincta seen from above

a forked organ turned forwards under the abdomen. When this is suddenly released, it strikes the surface on which the insect is standing and so throws it up into the air. They are common under stones, herbage, etc.

Some of the species are aquatic; and one, *Anurida maritima*, is fairly common on the sea shore. See Insect.

Sprinkler. Fire-extinguishing device. Water piping is laid on from elevated tanks or a pressure

Sprinkler. Diagram showing screw-in attachment. Top, sprinkler in action. See text.

supply, and this branches out into over-head parallel pipes extending from end to end of a building or room, and spaced at convenient distances apart. In each line of piping a rose or sprinkler is inserted at intervals and sealed with a composition which readily fuses. If a fire breaks out the heat quickly melts this composition and water is then sprayed out. A local fire may thus be extinguished without all the sprinklers coming into action. Valves are provided in the pipes so that the water may be cut off when no longer needed. Sprinklers are usually provided at the rate of one to about every 70 sq. ft. of superficial area. See Fire Brigade.

Sprinting. Short distance running. The sprint is regarded as one of the most strenuous of athletic events, as the utmost pace has to be maintained throughout the entire distance run. Although the most popular sprint distance is 100 yards, races of 60 yards, 75 yards, 120 yards, 220 yards, and even 440 yards are also classed as sprint races. The practice of short bursts of speed, from 30 to 40 yards, the maintenance of a long stride, and speed in getting off the mark are important factors in sprinting. The start should be made from a crouching position, with the hands lightly resting on the ground.

Not a few male sprinters have attained "evens," i.e. 100 yards in 10 secs. The world's amateur record for 100 yards is 9.3 secs., by M. E. Patton (U.S.A.), 1948. The women's record time is 10.7 secs., by M. Jackson (Australia), 1950. See Running.

Sprit Sail (A.S. *spréot*, pole). Sail which is extended by a sprit, or pole, reaching across the sail from the mast at the foot, to the peak. It can be raised, lowered, or brailled up very quickly. See Ship.

Sprocket. In machinery, a tooth or projection on the circumference

of a wheel. A sprocket wheel is one with cogs to engage with the links of a chain, as in the driving-wheel of an ordinary bicycle.

Sprocket wheel, with cogs a, a, a

Spruce (*Picea excelsa*). Evergreen tree of the family Coniferae. Native to Europe, it was introduced into Great Britain before 1548. It attains a maximum height of considerably over 100 ft., when planted in deep, rich loam. First planted in Great Britain as an ornamental tree, or behind young plantations of shrubs to act as

Spruce. Cones and scale-like leaves of the black spruce, *Picea nigra*

a nurse, the 20th century has seen considerable increase in govt. forestry plantations of spruce for its relatively quick yield of timber intended for use in aircraft construction. The timber is also useful for roofing, flooring, poles, and ladders, or for scaffold poles, masts, or pitprops. Black spruce (*P. nigra*), a small N. American fir, is largely used in the manufacture of paper pulp.

Spruce Beer. Alcoholic beverage. It is brewed from sugar or treacle and a decoction made from

Spurge. Yellow flowers and bracts of the wood spurge; right, leaves

the young shoots of the spruce-fir, fermented with yeast, and variously flavoured. The black beer of Danzig is a well-known variety.

Sprue. Disease occurring in hot, damp climates, characterised by dyspepsia, diarrhoea, sore tongue, anæmia, and wasting. The cause is unknown, but the condition arises from defective absorption of many vital food factors, including fat, from the bowel. A diet with high protein and low fat content is given, with liver injections.

Spur (A.S. *spura*). Sharp instrument fitted to the heel of a rider, to press into the side of a horse to urge it on. Modern spurs usually have rowels or little wheels edged with sharp points. At one time gold spurs were a sign of knighthood. The word is also a contraction for spur wheel, which consists of a circular disk having around its periphery metal, leather, or other teeth for gearing with another wheel or a toothed rack. The teeth are parallel to the axis of the wheel as distinct from, e.g. helical wheels, in which the teeth form portions of helices.

Spur. Ornamented spur of the 16th century. Top, types employed in cavalry and hunting

Spurge (*Euphorbia*). Large genus of trees, shrubs, and herbs of the family Euphorbiaceae. They are natives of all except the extremely cold climates. Most of them have milky, acrid juice, and many are succulent like cacti. Few of them have conspicuous flowers, but in some species, *E. pulcherrima*, the Poinsettia of

gardeners, for instance, the yellow blossoms are surrounded by large bracts which are brilliantly coloured red. Some of the European species are mere weeds of cultivated ground, but the wood spurge (*E. amygdaloides*) is a shrub-like perennial with large persistent leaves. Cypress spurge (*E. cyparissias*), another European species, is grown in garden borders.

Spurgeon, CHARLES HADDON (1834-92). British preacher. Born at Kelvedon, Essex, June 19, 1834, the son of

C. H. Spurgeon,
British preacher

an Independent minister, after a little education he was for a time a schoolmaster at Newmarket. Having joined the Baptist denomination, he became, in 1852, minister of a Baptist chapel at Waterbeach, where his success won for him, at the age of twenty, an invitation to a church in Southwark. There his preaching attracted great crowds, and after Exeter Hall and the Surrey Gardens music hall had been used for the services, the Metropolitan Tabernacle was built for him, 1860-61. There he preached until his death at Mentone, Jan. 31, 1892.

Eccentric and sensational in his appeals, possessing a fund of humour and a remarkable power of homely speech, Spurgeon was the most popular preacher of his day. His creed was of the narrowest, a Calvinism of the most unyielding type; rather than tolerate any departure from his views, he withdrew from the Baptist Union in 1887. He was, nevertheless, a great student, especially familiar with the writings of the Puritans. His activities included the foundation of a college for training Baptist ministers, an orphanage at Stockwell, and some almshouses. His sermons, published regularly, had an enormous sale, and his magazine, *The Sword and Trowel*, was equally popular. His other writings include *The Treasury of David*, and *John Ploughman's Talk*. One of his sons, Thomas, was pastor of the Metropolitan Tabernacle, 1892-1908. *Consult* *Autobiography*, 1897-1900; *Personal Reminiscences*, W. Williams, 1895; *Lives*, W. Y. Fullerton, 1921; J. C. Carlile, 1933.

Spurn Head. Promontory on the E. coast of the East Riding of Yorkshire, England. It extends 2½ miles into the estuary of the Hum-

ber and has two lighthouses. In 1864 groynes had to be erected to prevent encroachment by the sea, but this remains a constant threat. *See* Ravenspur.

Spurrey (*Spergula*). Genus of plants of the family Caryophyllaceae, natives of temperate regions. One species, *S. arvensis*, the corn spurrey, grows in Great Britain. It has stalks 6 to 12 ins. long, swollen at the joints, and panicles of white flowers. It is frequently grown as a sheep fodder. Sandwort spurrey (*Spergularia rubra*) and sea spurrey (*S. salina*) are British plants of an allied genus. Both have pink flowers.

Spurs, BATTLE OF THE. Fought near Thérouanne, between the English and the French, Aug. 16, 1513. Henry VIII was besieging Thérouanne. To relieve the hunger of its garrison the French planned to threaten the English with 8,000 men, while a small column rushed in supplies. The English learned of the scheme, and when the French appeared they found themselves in the grip of two forces. After a brief cavalry skirmish the French knights spurred away. Hence the name given to the encounter, in which Bayard was taken prisoner. Six days later Thérouanne surrendered.

Sputum (Lat. *spuere*, to spit). Material coughed up from lungs or air passages. *See* Expectoration.

Spy (Old Fr. *espier*, to espy). One who obtains prohibited information surreptitiously. A spy may be a national of the country requiring the information, who spies for patriotic reasons, or one who reveals his own country's secrets to a foreign power either for monetary reward or to further some form of ideology. In the last case, the spy is more correctly a renegade or a "fifth columnist." In theatres of military operations, a spy is distinct from a scout; the latter seeks information while wearing uniform, while a spy assumes disguise. A captured spy is ignominiously put to death, a scout must be treated as a prisoner of war. The employment of spies in wartime is recognized by international law, but the spy himself is regarded as an outlaw. In time of peace spies are employed by governments to detect internal disaffection, as well as to ferret out secret information about armaments and inventions; while large industrial undertakings frequently use spies to discover processes used by their trade competitors. *See* Espionage; Official Secrets Acts; Secret Service.

Spy. Pseudonym adopted by Sir Leslie Ward (q.v.), British caricaturist.

Squad. Military term for a small party of men. The term is usually applied to recruits who are grouped in squads for purposes of drill and instruction before being allotted to their various units. The awkward squad consists of recruits who find difficulty in learning drill.

Squadron. Military term for a sub-division of a cavalry or armoured regiment. A British cavalry regiment is divided into three or more squadrons, corresponding to an infantry company. Each is commanded by a captain, or a major assisted by a captain, and is sub-divided into two troops, each commanded by a lieutenant. Royal Tank regiments have four squadrons to the battalion, and Royal Armoured Corps regiments, which are mechanised cavalry, four squadrons to the regiment.

In the Royal Navy a squadron is a number of warships, smaller than a fleet, commanded by a flag officer for a special service or station. Cruisers and battleships of a fleet are divided into squadrons for operational purposes, when four ships of one particular type constitute a squadron. Vessels below cruiser category are organized in flotillas.

In the R.A.F. a squadron varies between 9 and 12 aircraft according to type, divided into three or four flights. Four squadrons make up a wing. A field squadron of the R.A.F.'s Regiment consists of one armoured, one rifle, one support, and one headquarters flight, totaling 360 officers and men. An R.A.F. Regiment A.A. squadron consists of four flights, each manning four Bofors guns.

Squadron Leader. Title in the Royal Air Force of an officer of a rank equivalent to that of lieutenant-commander in the navy and major in the army. The insignia of rank are three rings on the sleeve and epaulettes.

Squall. Sudden blast of strong wind, lasting for some minutes, frequently with a temporary change in direction. The wind may attain a velocity of 50-100 m.p.h. These violent fluctuations should not be confused with the normal gustiness due to friction with the ground, etc., and to local obstructions.

Squalls occurring simultaneously along an advancing line, sometimes several hundreds of miles long, constitute a line squall. The phenomenon is caused by a relatively cold mass of air undercutting

and replacing a warmer one; it thus indicates the arrival of the cold front of a depression. Usually such a storm makes its appearance with ragged, threatening clouds associated with a long roll of low black cloud in the shape of an arch, and beyond this a uniform light grey sky. As the roll of cloud passes overhead, heavy rain squalls, often with hail, thunder, and a sudden drop in the temperature, are experienced at the surface. Line squalls may take 24 hrs. to die away, but their rates of advance can be predicted fairly accurately; they generally travel across the British Isles from W. to E. In the U.S.A. violent line squalls occur over the central plains. Other examples of these storms are the pampero of S. America and the southerly burster of Australia. In some regions, e.g. the S. shores of the Mediterranean, the warm air current, usually the source of the precipitation, is dry and the so-called white squalls are characterised by absence of cloud. *See* Depression; Gust; Wind.

Squarcione, FRANCESCO (1394-1474). Italian painter, founder of the Paduan school of painting. Born at Padua, where he also died, he began work as a tailor and embroiderer, and was more than 40 when he opened his academy for painters. Most of the work attributed to him was done by his pupils, among whom was his adopted son, Mantegna. *Pron.* Skwar-cho-nay.

Square. Four-sided plane rectilinear figure having all its sides equal and all its angles right angles. It is a particular case of the parallelogram, and its area is a^2 where a is the length of a side.

Square root in mathematics is a quantity or function such that when multiplied by itself it gives a specified quantity or function. Thus the square root of 25 is 5, of $a^2 + 2ab + b^2$ is $a + b$, etc.

Square Rig. Sails set crosswise of a ship, and thus the opposite of fore-and-aft rig, in which the sails are set fore and aft. Full-rigged ships are mostly square rigged, and the term is widely applied to craft that have only a proportion of square sails among their canyars. *See* Polacca; Ship.

Squares, METHOD OF LEAST. In statistics and mathematics, a method of deducing the most probable result of a series of observations in measurement in cases where the arithmetical mean of a number of observations of the same quantity is the most pro-

bable value of that quantity. The adoption of the mean value of the observation is the simplest case. When the observed values depend on several unknown quantities the rule is to adopt such values for the unknown quantities as to make the sum of the squares of the residual errors of the observations as small as possible.

Squaring the Circle. In mathematics, the problem which requires the finding by geometrical methods of a square whose area is equal to that of a given circle. The problem is as old as Pythagoras, and was one of the famous problems of the ancients. It has been definitely proved by Lindemann to be insoluble. *See* Quadrature.

Squash (*Cucurbita maxima*). Annual herb of the family Cucurbitaceae. Its native country is unknown, but it is cultivated in all

Squash. Leaves and edible gourd

warm and temperate lands. It is a trailing plant like the vegetable marrow (*C. pepo*) with large, rough, lobed leaves, and large, bell-shaped, yellow flowers. The fruits are fleshy and edible. *See* Gourd; Pumpkin.

Squash Rackets. Game played in a similar manner to ordinary rackets, but on a considerably smaller court, which confines the game to two persons. The ball is of indiarubber, the size of a five ball.

The walls of the court are either of smooth wood or of cement, and the game is much slower than rackets, the walls not having the same amount of spring and life as those of a full-size court. Squash is governed by most of the rules appertaining to single rackets. Good service counts little towards successful play, which depends more on accurate placing of the ball. Squash grew in popularity as a game, and as a form of exer-

cise, in the years between the two Great Wars, and many new courts were built, e.g. at Ealing, Grosvenor House, Dolphin Square, etc., supplementing older and more famous club courts at Lord's, Queen's Club, etc. *See* Rackets; *consult also* The Game of Squash, Eustace Miles, 1901.

Squaw. Married woman of an American Indian tribe. Squawman is the name given to a white man who marries an Amerind woman, in order to obtain land within the Indian Reservation. *See* American Indians colour plate; Iroquois.

Squeers, WACKFORD. Character in Dickens's novel Nicholas Nickleby. He is a schoolmaster in charge of Dotheboys Hall (*g.v.*), typical of the questionable Yorkshire schools which Dickens had set himself to expose in that book, and which he helped thereby to make obsolete. Squeers is an ignorant, avaricious brute who starves and bullies the unwanted boys who form the majority of his pupils. He has a wife, who gives a daily dose of brimstone and treacle to the boys; a daughter, Fanny; and a spoilt son, Wackford. Nicholas, who goes to the school as an assistant master, thrashes Squeers before the boys.

Squib. Word used in several senses including (1) a small firework of cylindrical form charged with a composition throwing out a fountain of sparks ending with the explosion of a small charge of gunpowder; (2) miner's squib, a small cylindrical case filled with a slow-burning composition used to fire a blasting charge in mining. *See* Fireworks.

Squid. Name popularly given to the genus *Loligo* of the cuttles, found around the British coasts. The common species (*L. forbesii*)

Squid. Giant specimen of this cuttle fish, measuring 80 ft.

has a rather long, cylindrical body, a short head surrounded by tentacles, and two triangular "fins" on the hinder portion of the body. Active animals, able to swim rapidly backwards, they feed upon small molluscs and crustaceans. *See* Cephalopoda; Cuttle.

Squill. Dried bulb of *Urginea scilla*. The glycosides of squill act on the heart in the same way as those of digitalis, but the drug is mainly used as an expectorant. Red squill is used as a rat poison.

Squillace, GULF OF. Wide opening of the Ionian Sea in Calabria, S. Italy. It is 35 m. wide between Cape Rizzuto and Punta Stilo.

Squint OR HAGIOSCOPE (Gr. *hagios*, holy; *skopein*, to look at). In church architecture, a narrow opening or slit in a wall, enabling persons in the transept or elsewhere to see the elevation of the Host.

Squinting OR STRABISMUS. Defect of the eye. In it the visual axis of one of the eyes deviates from its proper position, with the result that the two visual axes cannot be directed simultaneously upon the same point. It is due either to paralysis or over action of one of the muscles which move the eyeball. The condition is common in children and is curable by special exercises for the eye muscles, or by a delicate operation. See Eye.

Squire. Shortened form of esquire (q.v.). The term is specifically applied by popular usage to the principal resident in an English village or country district, who is usually a justice of the peace.

The abnormal taxation which followed the First Great War led to many estates changing hands, and to a decline in the traditions of squirearchy, but their disintegration had set in earlier, for similar complaints were expressed by W. Cobbett in his Rural Rides. The squire is a popular character in English fiction from the days of Fielding, whose contrasted types, Squires Western and Allworthy, both in the novel Tom Jones, may be compared with Sir Roger de Coverley of The Spectator. See Esquire.

Squire, SIR JOHN COLLINGS (b. 1884). An English man of letters. Born at Plymouth, April

Sir John Squire, English writer

2, 1884, he was educated at Blundell's and Cambridge. As Solomon Eagle he contributed regularly to The New Statesman for many years, becoming literary editor of that journal in 1913, and editor 1917-18. In 1919 he founded a new literary monthly. The London Mercury, and edited it until it ceased publication in 1934. This periodical enabled

him to give practical encouragement and help in their development to many younger writers, some of whom found it an opening to later success. A prolific writer, he achieved high repute as poet, parodist, short-story writer, and critic. His parodies are found in Steps to Parnassus, 1913; Tricks of the Trade, 1917; and Collected Parodies, 1921. He also edited the English Men of Letters series of biographies, collaborated in writing the play Berkeley Square, 1926, and published two books of reminiscences. The Honeysuckle and the Bee, 1937, and Water Music, 1939. Squire was knighted in 1933.

Squirrel (Gr. *skia*, shadow; *oura*, tail). Genus of small rodents of the family Sciuridae. The common squirrel (*Sciurus vulgaris*) occurs throughout Europe and N. Asia; but the British variety differs considerably in colour and seasonal changes from its Continental allies. It is 8 ms. long in body, with a tail of 7 ins. In the winter the coat is brownish red on the head and back, grey at the sides, chestnut on the limbs, dark reddish-brown on the tail, and white on the under parts; and the ear-tufts are long and conspicuous. In the summer the grey disappears from the sides, and the sides of the tail become buff or even cream-coloured; while the ear-tufts are much reduced in size.

Squirrels are common in most wooded districts of England and Wales; but in Scotland and Ireland they are local and sometimes rare. They spend most of their time in the trees, and on the ground progress by a series of bounds. They build nests of leaves, grass, and bark in hollows and forks of trees, in which to rear the young, which are born in June. Large stores of nuts, etc., are laid up for the cold season; but these are generally distributed over several hiding-places instead of forming a single hoard. The animals hibernate in cold districts.

Squirrel. 1. The common red species. 2. The grey squirrel, an increasing pest in the U.K. 3. Indian palm squirrel

The grey squirrel (*S. Carolinensis*) is a N. American species. Introduced into Great Britain in the 19th cent., it became a pest, and is treated as such under the Agriculture Act, 1947. See Flying Squirrel; Prairie Dog; Sable.

The small, golden-haired S. American squirrel monkey (family Cebinae) is so called from the resemblance of its head to a squirrel's.

Squirting Cucumber (*Ecbalium elaterium*). Annual herb of the family Cucurbitaceae, native of the Mediterranean region. It has trailing stems, and heart-shaped leaves with toothed margins. The flowers are yellow, and the fruit is a small green prickly gourd. When ripe, the fruit parts from its stalk and violently ejects its seeds, together with the thin pulp surrounding them, through the base.

Srinagar. Capital of Jammu and Kashmir, the state whose conditional accession to India in 1947 led to a dispute between India and Pakistan. The town stands on both banks of the Jhelum, 5,000 ft. above sea level, 175 m. N.N.E. of Lahore, in the fertile vale of Kashmir. Quaint timber dwellings surround the palace and fort, and stretch along the river banks, which are joined by picturesque wooden bridges. The former manufacture of shawls and carpets is decayed. A stone temple crowns the hill, the Throne of Solomon, and a fort built by Akbar surmounts the hill, Hari Parbat. The town was formerly the hot weather capital of the Mogul emperors. In 1947 Indian troops occupied Srinagar to pre-

Srinagar, Kashmir. A view of the town, and capital of Jammu and Kashmir, on the banks of the Jhelum river

vent its capture by Pathan tribesmen. Pop. 207,787.

Srirangam. Town of Madras state, India, in Trichinopoly dist. It is situated on Srirangam Island in the Cauvery river, N. of Trichinopoly. There is a temple with 14 gate towers. Pop. 27,000.

Srivilliputtur. Town of Madras state, India, in Ramnad dist. It is situated S.W. of Madura on the road and rly. to Travancore. Pop. 31,195.

S.S. Troops. Branch of the German Nazi party army. The initials are an abbreviation for *Schutz-Staffel*, protective squadron, and the formation was organized in 1928 as an élite corps of Storm Troopers (*q.v.*). Only reliable and fanatical party members were admitted to the S.S., and after the purge of the Storm Troop organization in 1934 it assumed increasing importance. It was administered on strictly military lines, and at its peak had a strength of 450,000. Members, who wore black uniforms, enjoyed numerous privileges, but were subject to a strict marriage control on racial grounds. The S.S. provided Hitler's bodyguard and was under the direct command of Himmler. Many armoured and other élite formations of the German army had only S.S. personnel, and during the Second Great War these fought with outstanding courage and stubbornness, *e.g.* at Anzio, Italy. At the trials held at Nuremberg, 1945-46, the organization was judged to be criminal.

St. Abbrev. for saint. In this Encyclopedia, as in most works of reference, place names, etc., beginning with this abbreviation, *e.g.* St. Albans, are entered as though spelt Saint Albans. Saints themselves are described under their own names, *e.g.* Matthew. See also San, Santa, and Santo.

Stabat Mater (Lat., the mother was standing). Opening words, used as the title, of a Latin hymn on the Crucifixion. Of uncertain

authorship, it has been ascribed to Pope Innocent III (1161-1216) and to Jacopone (c. 1306). It is fairly certain that it dates from the 13th century, and was one of the hymns sung by the fanatic bands of Flagellants in the 14th century. By the 15th century it was used as a Sequence, and in 1727 it was recognized as liturgical by being included in the Roman Missal. There have been several settings by famous composers, notably those of Palestrina, Rossini, Verdi, Dvorak, and Stanford.

Stabiae. Ancient town and seaport of Italy, in Naples prov. It was adjacent to Pompeii, with which it was destroyed by the eruption of Vesuvius in 79. Here Pliny met his death. Near the site is Castellamare di Stabia (*q.v.*), where in 553 the battle between Narses and Teias terminated the power of the Goths in Italy.

Stability. Property of a body, or of a system of bodies or forces, by virtue of which there is a tendency to return to a position of equilibrium if there is any displacement of the body or the systems.

A body may be in stable equilibrium either at rest or in motion. In the former case the stability is static, in the latter kinetic. The former is a particular case of the latter. A body suspended from a point about which it can turn freely may be in equilibrium in two ways. Its centre of gravity and the point from which it is suspended must be in a vertical line. If the point of support is above the centre of gravity, then, when the body is displaced, the weight of the body tends to bring it back to its original position, and the position is stable. If, however, the centre of gravity is above the point of support, then any turning movement will tend to increase the displacement, and to move the body farther and farther away from its original position; the equilibrium is unstable. If centre

of gravity and the point of support coincide, the equilibrium is said to be neutral.

When a body is in a position of stable equilibrium, the potential energy is at a minimum. In unstable equilibrium any slight displacement tends to lower the centre of gravity, and the body's potential energy is at a maximum. What is true of bodies under the action of gravity only may be generalised so as to apply to the equilibrium of a body under the action of any system of forces, so that, by considering whether the potential energy of the system is at a maximum or a minimum, we can say whether the system is in unstable or stable equilibrium. Examples of moving bodies in stable equilibrium are a spinning top, gyroscope, etc. A top at rest on its point is an example of static instability and on its broad end of static stability.

Staccato (Ital., detached). Musical effect, gained by separating the notes by rests, although these are not written in the music. It is indicated in three ways, by placing above or below the notes (1) dashes (*spiccato*), in which the notes are shorter than the rests; (2) dots (*staccato*), in which the two are about equal; and (3) dots underneath a curved line (*mezzo-staccato* or *portamento*), in which the notes are longer than the rests.

Stachys. Genus of plants of the order Labiales. See Woundwort.

Stacpoole, HENRY DE VERE STACPOOLE (b. 1865). British novelist. The son of a clergyman at Kingstown (Dun Laoghaire),

H. de Vere Stacpoole, British novelist

Dublin, he was educated at Malvern and studied medicine, but abandoned practice for literature. He published several very successful stories, becoming famous with *The Blue Lagoon*, 1908, a sentimental romance of life on a South Sea island. This was made into a play in 1920 (Prince's Theatre, London), and more than one film version followed. Other books include *The Pools of Silence*, 1909; *The Street of the Flute Player*, 1912; *The Beach of Dreams*, 1919; *Golden Ballast*, 1924; *The Lost Caravan*, 1933. He translated Villon's *Poems*, 1913, and published a biography of Villon, 1916. *The Story of My Village* appeared in 1947.

Stade. Town of Germany, in Lower Saxony. It stands on the Schwinge, a trib. of the Elbe, 22 m W. of Hamburg. It has manufactures of cloth, flannel, leather, and rubber, iron foundries, and a trade in fruit. A Hanseatic town, it became the capital of a Swedish duchy in 1614, and was sold to Hanover in 1719. It was destroyed by fire in 1639. It lay in the British occupation zone after Germany's surrender, 1945. Pop. 20,000.

Stadium (Gr. *stadion*). Greek measure of length equivalent to about 582.5 English feet. This was

Stadium. Plan of an ancient Roman stadium. Top right, air view of the Wembley Stadium, Middlesex, opened 1923

the distance of the short race at Olympia, and the name came to be applied, first to the race, and then to the building in which the racing and the other contests, except the horse-races, took place, not only at Olympia but elsewhere. The stadium at Olympia was rectangular, but most of the others had one semi-circular end, near which was the goal. One or both sides were often fashioned from the slopes of a hill. The revived Olympic Games at Athens in 1896 were held in the old Athenian stadium, restored for the purpose. The word has been revived in modern times to describe various athletic grounds surrounded by tiered seats for spectators, especially in the U.S.A. The two notable examples of modern stadiums in the U.K. are the one at Shepherd's Bush, London, constructed in 1908 for the Olympic Games of that year, and forming part of the so-called White City originally laid out for the Franco-British exhibition of 1908; and that at Wembley, opened 1923 as part of the British Empire exhibition of 1924, and scene of the F.A. Cup Final from 1923 onwards. Wembley can accommodate 95,000 spectators; the White City 68,000. *See* Circus; Olympic Games: Rome; Wembley

Stadtholder (Dutch *stadhouder*, substitute, deputy). Chief magis-

trate of the United Netherlands. The title was originally given to the representatives of the Spanish crown in the Netherlands. After the revolt of the seven states from Spain, 1579, Friesland elected John of Orange as stadtholder, while the six remaining states chose his brother William the Silent (*q.v.*). The authority of the stadtholders was based solely on the powers delegated to them by the states. On the death of William's grandson, William III of England, in 1702, the descendant of John became stadtholder. *See* Netherlands; Orange.

Staël, ANNE LOUISE GERMAINE, BARONNE DE (1766-1817). French writer. She was born in Paris, April 22, 1766, daughter of the financier Necker, and at twenty became the wife of the Swedish minister, the Baron de Staël-Holstein, from whom, however, she was separated in 1798. Driven from France by the Revolution, she retired to her father's estate at Coppet, near Geneva, and though she returned to Paris in 1797, she was presently exiled by Napoleon. M. de Staël died in 1802, and in 1811 his widow married a Swiss officer, Albert de Rocca, and after travelling extensively settled in Paris on the fall of the Empire. She died there, July 14, 1817.

Madame de Staël's principal works are her early *Lettres sur Rousseau*, 1788; two sentimental novels of passion, *Delphine*, 1802,

and *Corinne*, 1807 (both studies of "la femme supérieure"); two long treatises, *De la Littérature Considérée dans ses Rapports avec les Institutions Sociales*, 1800, and *De l'Allemagne*, 1810; and the posthumously published *Considérations sur la Révolution Française*, and *Dix Années d'Exil*. Madame de Staël holds an important position in the history of French literature. By her cosmopolitanism and her social treatment of literature, she helped to break down the dogmatic criticism of the classic school, while she performed an even greater service for French readers by opening up to them the new world of German idealistic philosophy and romance.

Bibliography. Works, 17 vols., ed. Mme. Necker de Saussure, 1820-21; Lives, M. Norris, 1853; A. Stevens, 1881; A. Sorel, Eng. trans. 1892; *Portraits de Femmes*, C. A. Sainte-Beuve, new ed. 1869; *The Salon of Mme. Necker*, G. P. d'Haussonville, Eng. trans. 1892; Mme. de Staël: *Her Trials and Triumphs*, A. C. P. Haggard, 1922; Mme. de Staël and the U.S., R. L. Hawkins, 1930; Germaine de Staël: *The Woman of Affairs*, R. McN. Wilson, 1931.

Staff. Word meaning a stick, a variant being *stave*. It has several compounds, *e.g.* flagstaff and quarterstaff, while the pastoral staff has become a symbol of office. The main use of the word, however, is for those who assist *e.g.* a soldier or sailor in high command, or the workers in a business and kindred undertakings.

In modern warfare the general staff is the directing brain of an army or navy. The idea was developed by the Prussians, who were the first to maintain a regular staff in times of peace, its duties being to prepare plans of campaign and

Mme. de Staël, French writer
After P. L. Boulvier

arrange for feeding and transporting armies. In the U.K. an imperial general staff was created early in the 20th century. See Moltke; Stave; Strategy; Tactics; War.

Staff. Term in engineering for an instrument used with a surveyor's level or theodolite for reading varying ground levels. The modern staff can be extended for about 5 ft. 6 ins. in length to 14 ft. or more, and is divided throughout its length into feet and inches, or metres and decimals. It is placed vertically on the ground at a distance from the observer, who reads through his level or theodolite the level at which his instrument stands. After allowing for

Stafford, England. The castle, built on the site of a Norman stronghold. Top right, the church of S. Mary

the height, the difference in level of the ground at the two points is ascertained by subtraction.

Staffa. Island of the Inner Hebrides, Argyllshire, Scotland. Lying 6 m. N. of Iona, it is 71 acres in extent, and rises to a height of 145 ft. Its coast is remarkable for a number of caverns, the most notable being Fingal's Cave, the entrance to which is constructed of columnar basalt; it is 66 ft. high, 42 ft. broad, and 227 ft. long. The chief of the other caves, seven in all, are McKinnon's or Cormorants' Cave, Boat Cave, and Clamshell or Scallop Cave.

Staff College. An institution where officers are specially trained in the subjects required for staff and other senior appointments. By training officers in this way, it is possible to ensure uniformity in the theory of tactics and organization. British institutions are the Royal Army staff college, Camberley; the Royal Naval staff college, Greenwich; and the R.A.F. staff

college, Bracknell. The Imperial Defence College, Belgrave Square, London, trains officers and civilian officials in the broadest aspects of imperial strategy.

In 1946 was established an administrative staff college at Henley-on-Thames, to bring together men and women of executive responsibility from industry and commerce, trade unions, and central and local government, to study the common principles that underlie effective administration. Students are nominated by their employers. The principle of the staff college has been adopted by many large companies and corporations as a regular feature of their organization.

Stafford. Mun. bor. and co. town of Staffordshire, England. It stands on the little river Sow, 23 m. N.N.W. of Birmingham, and is served by rly. The principal churches are S. Mary's and S. Chad's. The former, a beautiful cruciform

Stafford arms

building with octagonal tower, mainly of the 12th century, was founded in 914, and was once a collegiate church. The latter contains Norman work. Stafford is a suffragan bishopric in Lichfield diocese. Other buildings include the shire hall, borough hall, guildhall, infirmary, technical college, William Salt library, and Edward VI grammar school. Notable old houses are High House, Chetwynd House, and the Swan Hotel, described by Borrow in *Romany Rye*. Stafford Castle is an uncompleted building overlooking the town: it occupies the site of a Norman stronghold. Stone Flat is a recreation ground.

Stafford is an important rly. centre and has engineering works.

Women's footwear and wood heels are principal manufactures. Salt is made and there are brine baths. Important in Anglo-Saxon times, Stafford appears as *Stadford* in

Domesday book, 1086. It was made a bor. c. 1206. It had its own M.P. till 1918, Sheridan being the member 1780-1806; Stafford and Stone now form a co. constituency. Izaak Walton was born here. Pop 36,500.

Stafford, WILLIAM HOWARD, VISCOUNT (1614-80). English nobleman. Born Nov. 30, 1614, fifth son of

Thomas, earl of Arundel, he was created Viscount Stafford, in 1640. He was one of the five Roman

Catholic peers denounced by the perjurer Titus Oates (*q.v.*), and was arrested and put on trial for high treason, Nov., 1680. Convicted after an unfair trial on the false witness of Oates

Viscount Stafford, English nobleman. After Van Dyck

and his fellows in the Popish Plot (*q.v.*), Stafford was beheaded on Tower Hill, Dec. 29, 1680.

Stafford House. Former name of the London mansion now known as Lancaster House (*q.v.*).

Staffordshire. County of England. With an area of 1,153 sq. m., it is one of the midland counties, lying somewhat to the west. Its surface is low or undulating save in the N., where the Pennines enter it, and on Cannock Chase. Axe Edge, on the Derbyshire border, is 1,684 ft. high. The chief river is the Trent, which rises in the county; others are its tributaries, Sow, Tame, Blythe, Churnet, and Dove. Rudyard Lake is in the county. In the N. is the district known as the Potteries; in the east is Cannock Chase, once a hunting ground, but now a coalfield; and in the S. is part of the so-called Black Country, with its coalfields and ironworks. Elsewhere agriculture is carried on, the chief branches being the rearing of cattle, the cultivation of wheat, barley, and oats, and dairy farming. The county is well served by rly. and canal.

Staffordshire. Map of this midland county of England, famous for its potteries, coal mines, and brewing

Stafford is the county town, but there are a number more populous, e.g. Stoke-on-Trent, Wolverhampton, Walsall, Smethwick, West Bromwich, Wednesbury, and Burton-upon-Trent. Smaller places which possess historic interest are Lichfield and Tamworth. In the co. are part of Dove Dale, a beauty spot, Tutbury with its ruined castle, Chartley with its wild cattle, Alton Towers, and Beaudesert. The university college of N. Staffs was opened 1950 at Keele, near Newcastle-under-Lyme. The co. includes six co. constituencies, and is in the diocese of Lichfield.

Before the Norman Conquest Staffordshire was part of Mercia. Much of it was then and later covered with forests, of which there are remains in Needwood. Coal was worked as early as the 13th cent. and in the 18th pottery making started. The two Staffordshire regiments are the North Staffordshire (q.v.) and South Staffordshire (q.v.). Pop. 1,431,359.

LITERARY ASSOCIATIONS. Izaak Walton was born at Stafford, but the county's chief centre of literary interest is Lichfield, where Samuel Johnson was born. His birthplace is preserved as a Johnson museum, and statues of him and his biographer, Boswell, are in the town

Lichfield grammar school has memories of many famous pupils, including, besides Johnson, Joseph Addison, Elias Ashmole, and David Garrick. Ashmole was born in the house next to that in which Johnson was born; and Garrick and Erasmus Darwin lived in adjoining houses in Beacon Street. Anna Seward is known as the Swan of Lichfield; Ella-stone, by the Derbyshire border, is said to be the Hayslope of Adam Bede. The Potteries district—the Five Towns (q.v.), now incorporated as the city of Stoke-on-Trent—formed the background of many of Arnold Bennett's earlier novels.

Bibliography. Victoria History of the County of Stafford, ed. W. Page, 1908; Memorials of Old Staffordshire, W. Beresford, 1909; Staffordshire Past and Present, J. W. Bradley, 1911; Staffordshire (The King's England series), ed. A. Mee, 1937.

Stag. Male of the red deer (*Cervus elaphus*). It is distinguished from the hind, or female, by the presence of antlers on the head, and is of larger size. See Deer.

Stag Beetle (*Lucanus cervus*). Popular name for a large lamellicorn beetle. The male has large mandibles, which bear some resemblance to the antlers of a stag. The largest British species of beetle, being sometimes over two inches long in body, it occurs locally in the S. counties of England; and the larvae live in decaying oak trees. See Beetles, colour plate; Insect.

Stage (Old Fr. *estage*, Ital. *staggio*, from Lat. *stare*, to stand). A floor or platform raised above the level of the surrounding ground for any purpose, and, specifically, the raised platform in a theatre on which a play is presented.

In its earliest crude form the stage was merely the table on which Thespis (q.v.) placed the actor, who thence addressed the chorus ranged at an equal height upon the steps of the altar of

Bacchus, the table (*eleos*) being separated from the altar (*thymelē*) by an intervening space. In the great theatre of Dionysus at Athens, the *skênē*, or stage, stood opposite the amphitheatre of seats, and on a level with the lowest row. In breadth it was nearly equal to the diameter of the semi-circular part of the *orchestra* (q.v.), and it was cut breadth-wise into two divisions. The front portion, called *logeion*, was a narrow parallelogram projecting into the orchestra, and, being the stand of the actors when speaking, was constructed of wood for better reverberation of the voice. The hinder portion, the *proscenium*, was built of stone to support the heavy scenery and decorations. Backed and flanked by lofty stone buildings, it represented externally a palace, and contained within rooms for the actors and receptacles for the stage machinery. In the central edifice were three entrances upon the *proscenium*, royal personages emerging from the ornamental portal in the middle, and inferior personages coming on from the side entrances. On each side of the *proscenium* ran high lines of buildings with architectural front, containing passages communicating with the stage and its contiguous rooms.

The elimination of the religious element from dramatic representations entailed the abolition of the chorus, with consequent occupation of the Greek *orchestra* by the audience, and was also responsible for enlargement of the stage to accommodate the entire company of actors. This was one of the respects in which the Roman theatre differed from the Greek, and is characteristic of the modern theatre. In these the notable features of the stage are its great depth, its rake, or slope of floor from back to front, to set all the actors in perspective view, and the great depth below and height above it, to permit of the raising or lowering of scenery and the utilisation of mechanical means of obtaining spectacular effects. The elaboration of these has given many devices of extreme ingenuity.

Panoramic scenery, moving upon an endless roller to give the illusion of lateral movement, and remarkable improvements in illuminants and lighting arrangements render possible effects unimaginable to the great stage craftsmen of the Greek classic drama. Essentially, however, their stage machinery seems to have included all that modern ingenuity has devised, and their stage to have been

adequate for the proper exhibition of dramas which are the models for all time. *See* Apron Stage; Drama; Theatre.

Stage, THE. British weekly journal devoted to the theatre in all its branches. It was founded in 1880 by Charles L. Carson and Maurice Comerford. The former was editor until 1900, the latter succeeded him until 1903. Later editors were Lionel Carson, son of the first editor; Bernard Weller, and (since 1943) S. R. Littlewood. The journal is still issued by the firm of Carson and Comerford, Ltd., from offices at 19-21, Tavistock Street, London, W.C.2.

Stage-coach. Public passenger conveyance, plying regularly by stages between two towns. *See* Coaching; Motor Coach; Posting.

Stage Society, THE. British society for the production of dramas of literary merit which otherwise appeared to have little prospect of securing performance. Founded in 1899, the Stage Society's first production was Bernard Shaw's *You Never Can Tell*, at the Strand Theatre, London, May 2, 1900. Among other famous plays first produced under the auspices of the society was *Journey's End*, by R. C. Sherriff, in Dec., 1928. The society's activities lapsed after 1939.

Staggered Hours. A term applied to a proposed device for spreading the load of passengers on local transport services during rush-hours, by varying the starting and finishing times of work in different undertakings. In London buses, trams, and railways in 1947 carried on weekdays between 8 and 9 a.m. and between 5 and 5.30 p.m. several millions of passengers; far more than could be dealt with efficiently by the resources of vehicles, rolling stock, and officers. Extensive publicity campaigns failed to produce any appreciable "staggering," and a representative committee was set up in 1947 to arrange it systematically with individual employers. The same problem arose in most provincial centres.

The concentration of the holiday season into three months of the year presents similar difficulties even more serious, particularly since the passing of the Holidays with Pay Act, 1938. Pressure on seaside accommodation was lessened by staggering holiday weeks in towns and by the individual employers in fixing holiday weeks outside the month of August.

The necessity for the staggering of hours of work was emphasised

by the post-war experience of the electricity grid system. Consumption of electricity, both domestic and industrial, vastly increased after 1939; but facilities for providing electricity had decreased rather than increased owing to the cessation of all new construction and arrears of repairs during the war. The load, however, varied considerably from time to time during the day. To avoid complete breakdown of the system various forms of compulsory staggering of the load were introduced as a temporary measure, some factories, having even to transfer certain shifts from day to night.

Staggers. Complaint affecting horses and sheep. It is characterised by trembling, swaying, or falling due to imperfect coordination of the voluntary muscles, and has various origins. In sheep it may arise from louping-ill, or from the presence of hydatids in the brain. In horses staggers may be due to indigestion and constipation, to heart failure, diseased blood vessels, or to tumours on the brain. *See* Horse; Sheep.

Stag-horn Moss (*Lycopodium clavatum*). Popular name for certain club-mosses. *See* Club-moss.

Staghound. Name given to several breeds of hounds used for hunting the stag. The old English staghound, now thought to be extinct, was a variety of bloodhound, a large heavy animal with short broad head, pendent ears, dewlap, and heavily fringed tail. There were two strains, the northern and southern. The modern staghound is a large foxhound (*q.v.*), trained for the special work of stag-hunting. About a dozen packs exist in England, and a few in Ireland. The name staghound is also sometimes given to the Scottish deerhound.

Staghunting. Form of the chase common from ancient times in England and other countries. There are three kinds of deer in England which are hunted with hounds: the red deer on Exmoor, in Yorkshire (Ribblesdale), and in the New Forest; the fallow buck in the New Forest; and the roe deer in Dorset. Carted deer are also hunted in various districts.

The quarry is a "warrantable" deer, *i.e.* one old enough to be hunted, if possible, a hart, *i.e.* a stag of five years old or upwards, the object of the huntsman being if possible to kill the oldest deer. If, however, a one-horned stag, a hornless stag, or one with spike horns is known to haunt a covert, he is always killed if possible. In

the early hours the harbourer tracks the stag to the coverts, where it lies up for the day. The stag to be hunted must be separated from the others. For this purpose from two to nine couples of hounds, known as tufters, are taken to the covert, where, perhaps after two or three hours, more or less, they force the stag into the open. Then the tufters are stopped and the pack brought up from some convenient barn or stable in which it has been shut up. The tufters, released, pick up the line, and soon the whole pack is stretching away over the heather.

The chase takes from 40 minutes to two or three hours. Unless the stag beats the pack, he is generally brought to bay in a stream, where a rope is thrown over his antlers, and a keen knife ends the chase. Stags are hunted from Aug. 12 to Oct. 8, hinds from Nov. to Christmas or later. Generally about Easter the master devotes ten days to hunting the young deer, three and four years old. *See* Dog.

Stagira or **STAGIRUS.** Ancient town of Macedonia. It was situated on the Strymonic Gulf, and its site is occupied by the modern village of Stavro. It was founded in 655 B.C. by a colony from Andros, and became celebrated as the birthplace of Aristotle (*q.v.*).

Stahl, GEORG ERNST (1660-1734). German scientist. Born at Ansbach, Oct. 21, 1660, he was

G. E. Stahl,
German scientist

appointed to the chair of medicine and chemistry at Halle university, 1694. Stahl became one of the foremost chemists of

his generation,

and wrote many books on chemistry in which he showed the fallacy of many scientific ideas of his time. He was one of the exponents of the phlogiston theory (*q.v.*). He died in Berlin, May 14, 1734.

Stained Glass. Strictly speaking, any glass coloured either in process of manufacture or by subsequent treatment. In practice, the term is confined to the art and craft of making windows of glass thus coloured.

Glass stained in the making is termed "pot metal," and the earliest windows consisted essentially of pieces of coloured glass bonded together by lead strips which also supplied the outline of the design.

The manufacture of coloured glass was understood in very early times, but as windows played little part in early civilization it was not until the great architectural revival of the 11th century that the stained-glass worker had full scope for his genius. The art had not wholly disappeared during the interval, but no glass windows earlier than the end of the 11th century exist. The oldest are at Le Mans (c. 1090) and Augsburg (possibly 1065). In England the earliest window is claimed for several parish churches. Brabourne, Kent, has a window evidently early 12th cent., and Rivenhall, Essex, has pieces which may be earlier. English glass of importance begins in the 13th cent.

By A.D. 1134 the use of stained glass had become sufficiently lavish to provoke the Cistercian edict prohibiting the use of any but "white glass." This had the effect of fostering the art of grisaille, i.e. windows consisting of "white glass" decorated with a pattern in the "brown pigment" and relieved by occasional insets of coloured glass. Early "white glass" invariably had a faint greenish tint and a silvery opalescence, and with the skilful use of lead and stain the grisaille window is one of the most exquisite products of the Middle Ages. The five great lancet windows of York Minster provide one of the finest examples of the art. These "Five Sisters" have an area of 1,250 sq. ft. and contain nearly 100,000 pieces. Other examples of grisaille are at Salisbury Cathedral.

By the 15th cent. the stained-glass maker had achieved some of his greatest triumphs. The finest

specimens are in the great French cathedrals, notably Chartres, but York Minster may claim to possess perhaps the most remarkable in its great east window (200 panels of subjects, comprising 78×33 ft.). This is rivalled by the great east window of Gloucester, 72×38 ft., which is somewhat older—about 1350. The York window was made by John Thornton of Coventry, 1405.

After the 15th cent. the use of enamels as a means of colouring becomes increasingly prominent and the

stained glass depends much upon the conditions of treatment. Iron will give shades from yellow to light blue, and copper from ruby to greens. Early glass workers were never quite certain of the results. There was also considerable variation in the thickness of glass.

Yet it was by taking advantage of these defects that the medieval craftsman achieved a unique quality in his productions. When the craft was revived in the 19th cent. the interest in medieval glass was such that the glass-maker sought to devise means of reproducing the "defects" which his predecessors had so laboriously eliminated.

An important modification of pot metal is "flashed" glass. If the blowing tube were dipped first in one colour and then in another,

the final sheet had a thin film of the second colour on the outside. This appears to have been done from the earliest times in the case of red, as red glass alone is too heavy and intense in colour. The extension of the practice to other colours naturally followed, and after the 14th cent. such combinations were freely used. Even more ambitious schemes involving four or five colours were attempted, not always with the happiest results. The use of "flashed" glass afforded a means of producing a two-colour design in a single sheet of

Stained Glass. Assembling pieces of coloured glass on to an outline of the original design, seen in the background. Top, painting the pieces of glass already cut to pattern

stained-glass window tends increasingly to become merely a picture on glass, the qualities inherent in the nature of the materials being ignored.

The art degenerated as the technical resources improved. Judged by scientific standards, early glass was full of defects. The sheets were small, and were made by blowing a cylinder of glass and cutting it open down one side. It was then placed in a heated chamber and allowed to open out on a flat surface, thus forming a sheet. The under-side naturally showed the irregularities of the surface upon which it lay, while the upper surface had the characteristic striations produced during the blowing. Further, the means of fusion were not sufficiently under control to ensure regularity of colour and freedom from bubbles. The colour of

glass without the use of lead, by abrading one layer. This was a laborious process until the discovery of the value of hydrofluoric acid as an etching material, after which it became a simple practice, and consequently almost a matter of routine in the glass workers' factory.

The possibilities of design with pieces of coloured glass outlined by lead are clearly limited. With the desire to produce pictorial and more or less naturalistic designs, the use of some kind of paint or enamel was imperative, e.g. in depicting human features or the folds of a robe. This was effected by the use of a brown enamel consisting essentially of iron oxide mixed with a glass somewhat more fusible than the sheet. The design was painted in and the sheet again fired. This was used for shading and fine work, and is artistically in a different category from the

coloured enamels which later were used specifically as colouring agents.

In the 14th cent. it was discovered that silver salts fired on the glass gave a wide range of yellow stains, from a delicate primrose to an intense orange. This, together with the brown pigment, gave the artist full scope for resplendent work.

In 15th century windows, design is stronger, drawing and shading more delicate, and the proportion of white glass increases. The sheets of glass are larger and white glass clearer, whilst in flashed glass variation in the thickness of the coloured layer is less marked.

Decline and Revival

Many factors led to the decline of the art. The Renaissance and the Reformation ended the long reign of the Church as almost the sole patron of the art. Reformers were interested in destroying rather than creating stained glass. On the other hand, the improvement in domestic and secular architecture opened new fields for the stained-glass worker. New aesthetic standards were created and a wider range of subjects was open to the artist. The greatly increased range of enamels gave him freedom from the limitations of leaded glass. This fact led to the painted window rather than the stained-glass window. Reynolds's famous windows in Oxford are typical.

Glass work fared better on the Continent. In Holland the work of the Crebeth brothers is outstanding. In Switzerland an interesting development was what is sometimes called "needlework." The glass is covered with a layer of paint and the design, often very elaborate, is scratched out with a needle. The Swiss were particularly successful in producing an enamel which did not tend to break away from the glass in course of time. In France and Germany much beautiful work was done, but the designs would look at least as well on an opaque background: they are designs transferred to glass, not designs in glass.

The middle of the 19th century brought a revival of interest and a steady progress, largely due to the work of C. Winston, who first investigated the properties of medieval glass upon which its peculiar artistic potentialities depend. The work of John Clayton deserves special mention, for he and his school were responsible for many fine windows, notably at Truro

Cathedral, King's College Chapel, Cambridge, and St. Augustine's, Kilburn. Burne-Jones also deserves mention as an artist who appreciated the peculiar nature of stained glass.

No wholly satisfactory system can be devised for the classification or chronologic division of the art. Three nations are pre-eminent—France, Germany, and England. It is usually said that France was supreme in the 13th and 16th cents. and England in the 14th and 15th, but even here the typically English grisaille windows challenge comparison with work elsewhere at any period. In Germany on the other hand there is an unbroken record of high achievement from the 11th cent. to the middle of the 16th.

There is also a marked difference in the way the art developed in the various countries. In Germany a certain conservatism led to a lagging in the adoption of new artistic styles, and throughout there is a tendency towards richness of colour and breadth of treatment. In England the 13th cent. was marked by the extensive use of clear glass (grisaille), so that in the succeeding period English glass tended to become richer in colour whilst in France and Germany the tendency was the other way. In France the reaction went rather too far. In Germany a compromise was effected by confining the rich colouring to the lower part of the window and glazing the upper portion in white glass. The "Geometric" style, in which white glass was covered with geometrical designs, is also characteristically German. Later, when the Gothic style was adopted in Germany, the effect of perspective was assisted by filling the characteristic canopies with small figures between and behind the pillars, hence the name "Interpenetrated," which corresponds roughly with Late Gothic in England. In France, the period and styles similar to English Perpendicular are termed Flamboyant.

For English glass the usual division is more or less according to architectural style. *Early English* up to about 1280; *Decorated*, 1280–1380; *Perpendicular*, 1380–1500; *Renaissance*, 1500–1550. A more general classification corresponds very closely to the centuries. *Romanesque* up to about 1300, the characteristic window being the medallion mosaic in which small pictures are surrounded by ornamental frames; *Early Gothic*, 1300–1400, charac-

terised by the introduction of silver stain and simple canopies but without any attempt at perspective (German Geometric comes in this period); *Late Gothic*, 1400–1500; *Renaissance* after 1500.

The study of stained glass is necessarily based mainly upon that in cathedrals, but even in medieval times it is clear that there was much stained glass in private houses. Chaucer's description of his room with windows in which "wholly all the story of Troy was in the glazing y-wrought" is an example. In addition, heraldic windows naturally figured largely in medieval art, and relics of many such windows are still to be seen.

Westlake, 4 vols., 1881–94; The Journal of the British Society of Master Glass Painters contains valuable papers; and C. H. Sherrill's Stained Glass Tour series (England, Germany, France, Italy, Spain) gives a vivid general picture of the art in each country.

Stainer, JAKOB (1621–83). German violin maker. Born at Absam, near Innsbruck, July 14, 1621, he became a protégé of the archduke Ferdinand Charles from 1648 onwards. He was a highly successful maker of the violin, viol, viola da gamba, and other instruments, but had pecuniary disputes and died penniless and insane in 1683. Similar to the Amati violin, though less graceful, the Stainer commands a fair price, but is not so keenly sought as during the early 19th century. Jakob's brother Markus was also an able maker, but his instruments are very rare.

Stainer, SIR JOHN (1840–1901). British composer. Born in London, June 6, 1840, he was a chorister in St. Paul's cathedral, 1847–56, and in 1859 went to Oxford as university organist. He was organist of St. Paul's cathedral, 1872–88, and, knighted in 1888, became professor of music at Oxford in 1889. He died at Verona, March 31, 1901, and was buried in Oxford. An organist of great ability, he was also a composer of merit. Among his works are the oratorio Gideon, the

Staines. Urban dist. of Middlesex, England. It stands on the left bank of the Thames, where the Colne flows into it, 19 m. from London. It has two rly. stations, and is also served by coach and bus from London, for which it serves as a riverside resort as well as an outer residential dist. Staines itself is a market town, but the urban dist. also includes Ashford, Stanwell, and Laleham. The chief buildings are S. Mary's church, rebuilt 1828, and enlarged 1885, with a fine peal of bells, and S. Peter's, 1894, built at the expense of Sir Edward Clarke.

Staines was a Saxon settlement, the name meaning stone, an important boundary stone (now in a recreation ground) being here from early times. For many centuries there has been a bridge across the Thames at Staines, the granite structure by Rennie being opened in 1832. The trial of Raleigh in 1603 took place in the old market house here. Near by is Runnymede (*q.v.*). Pop 37,600

Stainforth, GEORGE HEDLEY (1899-1942). A British airman. Born at Beckenham, he was educated at Dulwich and Sandhurst. As a flight-lieut. in the R.A.F., he was selected in 1928 for duty with the high speed flight. In 1929 he created a new world speed record of 336.3 m.p.h., and in 1931 represented Great Britain in the final race for the Schneider Trophy (*q.v.*), with an average speed of 379.05 m.p.h., only to beat this a few weeks later with 407.5 m.p.h. He received the A.F.C., and after service with the aircraft carrier *Glorious* and in Iraq he was promoted wing commander in 1940, and was killed in action over Egypt, Sept. 30, 1942, being buried in the British cemetery, Ismailia.

Staining. In a special sense, the treatment of wood with preparations which colour it without hiding the natural grain. The several types of preparations may be classified as follows:

(1) Chemical, *e.g.* treatment of wood with a solution of permanganate of potash, which produces a brown colour; or "oak" stain, produced by using a solution of sodium bichromate and ammonia tinted with vandyke brown. (2) Water stains, *i.e.* solutions of shellac in alkali (usually borax) and suitably tinted with dye. (3) Spirit stains, *i.e.* those based on a solution of

resin (especially manila copal) in methylated spirits, possibly with added dyes. (4) Coal tar stains, *i.e.* coal tar and coal tar distillates, such as are often used on out-buildings and places exposed to damp. (5) Oil stains, in which pigments such as siennas and umbers are ground in a hard drying varnish and diluted as required with a suitable thinner, *e.g.* turpentine or white spirit.

Stair, EARL OF. Scottish title held by the Dalrymple family since 1703. James Dalrymple, a lord of session, was made Viscount Stair in 1690 and was succeeded by his son John, who was lord justice clerk and lord advocate, and was created earl of Stair in 1703. His son John, 2nd earl, was a distinguished soldier and ambassador to France, and on his death, without heirs, in 1747, the succession to the title was disputed. The matter was settled in favour of James, nephew of the last earl. He also died without heirs, and the title passed through various successions to North Hamilton, 9th earl (d. 1864), from whom subsequent holders of the title are descended. The eldest son is called Viscount Dalrymple.

Stair, JOHN DALRYMPLE, 2ND EARL OF (1673-1747). Scottish soldier and diplomatist. Born July 20, 1673, second son of the 1st earl, he first saw military service under the prince of Orange in Holland, and later served under Marl-

2nd Earl of Stair,
Scottish soldier

Stalactites and stalagmites in
Cox's Gavern, Cheddar

Stairs OR STAIRCASE. Part of a building containing steps, leading from one floor to another, or from the ground to the entrance. The staircases of Greek and Roman architecture were constructed in the thickness of the walls. Those of the Middle Ages also, straight or spiral in form, were placed in inconspicuous positions. A medieval castle would be provided with a number of them, the steep, winding course of each being carried up the wall of a turret or buttress. The monumental exterior type is of classic origin, and was developed to the full in the Middle Ages. The ornamental staircase dates only from the latter part of the 16th cent. The square-planned or well staircase began to appear in the early 16th cent., but it was of the plainest character till the reign of Elizabeth.

Then a development took place in form and ornament. Although the corkscrew or spiral type was still retained in places, and certain splendid mansions, such as Hardwicke Hall, were content with plain flights of steps, the broad wooden staircase, with short flights connecting the landings, became the general rule. These were stoutly constructed with thick wooden balusters and massive handrails, the newels being carried up very high and finished with decorative finials. Crewe Hall, Hatfield House, and Cold Overton possess specially handsome staircases of this period. In the 18th century the height of the newels was reduced, the ornament simplified, and the whole construction became lighter. See illus p. 7742.

Stakhanovite. In communist countries a term applied to a worker or group of workers responsible for some exceptional feat of industrial output. It derives from the name of Alexei Grigoryevich Stakhanov (b. 1905), a Donbas miner, who in 1935 hewed 102 tons of coal (about 16 times the normal output) in one shift. In 1941 he was put in charge of a govt.

dept. for encouraging "socialist competition" among miners.

Stalactites AND STALAGMITES (*Gr. stalaktos, stalagmos*, from *stallassein*, to drip). Calcareous masses, usually conical or cylindrical in shape, formed by drippings from the roofs of caves. Water which

devoted himself to the improvement of his estates and to political machinations against Walpole, but in 1742 he was made a field-marshal and played a conspicuous part in the battle of Dettingen. He died in Edinburgh, May 9, 1747. See STRAUNER.

Stairs. Examples from English country houses. 1. Elizabethan oak staircase in the east tower, Grove Place, Hampshire. 2. Early Georgian, Finchcocks, Goudhurst, Kent. 3. Modern Classical, Fulbrook House, Farnham, Surrey. 4. Early Stuart (1619) open well staircase, with finely carved figures on the newels, Blickling Hall, Norfolk

has passed through limestone contains dissolved carbonate of lime. This water may find its way to the roof of a cave, and thence drip to the floor. Each hanging drop is partly evaporated, and leaves behind a little carbonate of lime; successive drops leave more lime,

until an icicle-like pendant is formed. These stalactites are found in limestone caves; *e.g.* in England in the Peak and Cheddar districts.

Stalagmites are calcareous masses upon the floors of caves. They gradually grow on the spot where water containing dissolved

carbonate of lime drips from the roof, usually from a stalactite. *See* Jenolan Caves.

Stalag. Contraction of the German *Stammlager*, prison camp. It was used in the Second Great War to denote German prison camps for captive n.c.o.s and men. *See* Oflag.

Stalagmite. Calcareous accretion from the floor of a cave. It is described under Stalactite.

Stalbridge. Town of Dorset, England. It is 6 m. from Sherborne, with a rly. station. The chief occupations are found in the timber yard and glove factory.

The principal building is S. Mary's church, and there is a large market cross. Stalbridge is mentioned in Domesday book. Pop. 1,400.

Stalin. Name given in 1949 to the Bulgarian seaport formerly known as Varna (q.v.).

STALIN: LEADER OF THE U.S.S.R.

George Soloveytschik, Author of *Russia in Perspective*, etc.

This biography of Lenin's successor, who on Lenin's death triumphed over all his former leader's other associates, should be read in conjunction with Russia: History, and the biographies of other notable Bolsheviks: e.g. Bukharin; Lenin; Molotov; Rykov; Trotsky; Vysinsky; Zinoviev

Joseph Vissarionovich Stalin, prime minister (from 1946) and generalissimo (from 1945) of the U.S.S.R., and general secretary of the central committee of the Communist party (from 1922), was born on Dec. 21, 1879, in the small Caucasian town of Gori, near Tiflis. (Tbilisi). His real surname was Djughashvili, and Stalin is only one of the many adopted names he used throughout his long career as a professional revolutionary. *Stal* is Russian for steel, and the connotation presumably was originally intended to indicate his strong character.

Stalin's father was a Georgian peasant who eked out a miserable living first as a cobbler at Gori and then as a worker at the Adelskhanov shoe factory in Tiflis. The mother, likewise of Georgian peasant stock, was Catherine Geladze; she died in 1937, aged 78. She had had three children before Joseph, but they had all died in their infancy. Her entire affection became concentrated on the fourth-born, Soso (Caucasian pet name for Joseph), whom she dreamt of dedicating to the priesthood, while the father wanted the boy to be a cobbler like himself. The father died when Soso was 11, and he remained entirely in his doting mother's care. A violent attack of smallpox nearly killed the boy and left him pockmarked.

When Soso was 14, his mother obtained for him, with difficulty, a scholarship at the Greek Orthodox (Church of Russia) theological seminary in Tiflis. He spent five years there, but instead of developing an interest in religion, he was attracted by Marxism and revolutionary doctrines. In 1896 and 1897 he conducted Marxist study circles among his school-fellows, and the following year he formally joined the Tiflis branch of the Russian Social Democratic party. While still at school he adopted the first of his many pseudonyms, Koba, which was the

name of a popular romantic Caucasian hero. Other pseudonyms included David, Nijeradze, Chizhikov, and Ivanovitch; but Stalin is the one he bore longest and under which he entered history.

Joseph Stalin, leader of the U.S.S.R.

In 1898 he was expelled from the seminary, and from then onward he devoted all his time to revolutionary activities. During the next two or three years he concentrated on propaganda among the working men of Tiflis and other Caucasian industrial centres.

In 1901, the police authorities issued their first warrant for his arrest, but he managed to go into hiding and continued his work underground. The following year he organized an important strike at the Rothschild and Mantashev oil works and on April 5, 1902, he was arrested. Between 1902 and 1913 he was arrested seven times and exiled to Siberia six times. Five times he managed to escape.

During 1901-17, whether in or out of gaol, whether living in exile or working in the revolutionary underground (mostly in the Caucasus but at times also at St. Petersburg), Stalin was an active member of various Social Democratic organizations but nevertheless remained a very inconspicuous figure in the movement. He happened to be in prison in 1903 when he heard of the split between the Bolshevik and Menshevik wings of his party, and he promptly associated himself with the Bolsheviks. In Dec., 1905, Stalin met Lenin while attending, as a delegate from Transcaucasia, the first all-Russian Bolshevik conference in Tammerfors, Finland.

Despite the claim of his official biographers that he became one of

Lenin's closest associates there and then, or indeed that the two men had been working in constant personal contact before actually meeting, there is no evidence at all of a close working relationship until after the Bolshevik revolution in Nov. (Oct. old style), 1917. He was just one of many revolutionary agitators and terrorists, but nowhere near the top even in his own Bolshevik group.

Stalin attended the fourth congress of the Russian Social Democratic party in Stockholm in 1906, and the fifth in London in 1907, when the final rift between the Bolsheviks and the Mensheviks occurred. Apart from two other short trips abroad in 1912, when he visited Lenin in Cracow and also stayed a few days in Vienna, these are the only known occasions when Stalin ventured outside the Russian empire. The detail is important, because it distinguishes him from most of his revolutionary colleagues, who spent many years as exiles in western Europe and in America.

Arrests and Escapes

Escaping from Siberia to St. Petersburg early in 1912, Stalin took a certain part in organizing the May Day demonstrations, wrote some articles in the clandestine Bolshevik press, and participated in the secret, illegal preparations of his party for the coming elections to the fourth duma. On April 22, 1912, he was arrested in the street and banished again for a period of three years; but he managed to escape once more and in Sept. of the same year he was back in the capital. Together with Molotov, he directed the Bolshevik campaign in the duma elections, and when these were over continued to work with the group that had been elected. Re-arrested for the sixth time on Feb. 23, 1913, he was banished once more, and in Dec., 1916, he was about to be called up for the army. While travelling S. under police escort, he heard the news of the Feb., 1917, revolution and he hastened to Petrograd—this time a free man, capable of openly engaging in political activities as a member of the central committee of the Bolshevik party.

He contributed actively to the overthrow of the Kerensky govt., was a member of "The Five" during the October revolution, and afterwards of "The Seven"—thus being associated with Trotsky, Zinoviev, Kamenev, and the other famous Bolshevik leaders whom he later destroyed. From the

inception of the soviet govt. until 1923 he was people's commissar for nationalities. In 1918-20 he was also extremely active in the civil war, winning great fame by his defence of Tsaritsyn (renamed Stalingrad) against the Whites. In March, 1919, he was appointed by Lenin people's commissar for state control, a dept. later reorganized as people's commissariat of workers' and peasants' inspection.

At the 11th congress of the Bolshevik party (March-April, 1922) Stalin was elected general secretary of the central committee—a position he used to make himself dictator not only of the party but of the U.S.S.R. He was proposed for this post by Zinoviev, but significantly enough his official biographers claim that Lenin proposed the appointment.

When Lenin died in 1924, it was as yet by no means certain who would succeed him as the most powerful man in Russia. Stalin's position was a strong one, but Trotsky was generally considered as Lenin's most obvious successor. Moreover, there were many other leading Bolsheviks—e.g. Zinoviev and Kamenev, Rykov and Bukharin—who had been very close to Lenin, who were far better known than Stalin, and who were by no means certain to accept him as their new master. Indeed, a life and death struggle between these various groups and individuals broke out almost forthwith, and lasted 14 years. For it was only with the biggest and most brutal purges of 1938 that Stalin removed the last of the Bolshevik "Old Guard," destroying them one by one. Trotsky was the earliest victim; after banishment, then expulsion from Russia, and untiring persecution all over the globe, he was finally assassinated in Mexico. The others were made to appear at endless trials, were forced to accuse each other of the vilest crimes, to "recant," to "confess" the most fantastic "sins." They were physically destroyed on a scale unprecedented even in Russia.

While this struggle was raging, Stalin in 1926 published his book, *On the Problems of Leninism*, which exposes very freely his political philosophy and offers many valuable clues to his mind and character. He is a dull but prolific writer and orator, and speaks Russian with a strong Georgian accent. All his articles and speeches are available in print not only in Russian but in more than 100 different languages.

Stalin, with an interpreter, greeting Winston Churchill on arrival at Potsdam for the conference with President Truman, July 17, 1945

British Official

He was elected a member of the presidium of the supreme soviet of the U.S.S.R. in 1925, and continued to hold that position. He also became a member of the *politbureau* of the Bolshevik party, a member of the council for labour and defence, was chairman of the committee for drafting the soviet constitution in 1935, and chairman of the council of people's commissars from 1941 to 1946, when the name of this office was changed into that of president of the soviet council of ministers.

He took an extremely active personal part first in preparing Russia's national defences and then in directing her whole war effort in all its aspects—military, economic, political, and diplomatic. Indeed, it can be said that the three five-year plans which preceded the war were, among other things, instruments for the industrial organization of the country with a view to a military emergency.

Throughout the hostilities, when most of the soviet govt. was evacuated to Kuibishev, Stalin remained in Moscow. In Nov., 1943, he travelled to Teheran for a conference with Churchill and Roosevelt, this visit to Persia being his first journey abroad since 1912.

Stalin held many honorary ranks and titles in the U.S.S.R., including the order of the red banner (1919), the order of Suvorov (1943), the order of victory and order of the red banner (1944), order of victory and title of hero of Soviet Union, as well as the order of Lenin and medal of the gold star (1945).

Bibliography. Lives, I. D. Levine, 1931; S. Graham, 1931; H. Barbusse, Eng. trans. V. Holland, 1935; O. Ray, 1939; D. M. Cole,

1942; E. Yaroslavsky, 1942; J. T. Murphy, 1945; L. Trotsky, 1947.

Stalinabad. Capital of Tadzhik S.S.R., centre of Stalinabad region. The former Dushambe, it lies in the W. of the Tadzhik republic, about 100 m. N. of the frontier with Afghanistan. It is connected by air with other towns of the republic, and with Moscow and Vladivostok; by rail with Termez, and by motor road, completed 1940, with Khorog in the Pamirs. It is a cotton manufacturing town. Pop. (1939), 82,540.

Stalin Canal. Most northerly section of the Baltic-White Sea canal (*q.v.*), R.S.F.S.R. It was completed in 1933.

Staliner. Capital of the South Ossetian autonomous region of the Georgia S.S.R. It lies 55 m. N.W. of Tbilisi, the capital of Georgia.

Stalingrad. City of the R.S.F.S.R. It lies on the river Volga 240 m. from its mouth, and is the chief town of the region of the same name. Formerly called Tsaritsyn, it was in 1918 the scene of the defeat of Denikin's White Russians by the Red army under Stalin's leadership; and its name was changed in his honour. Between 1922 and 1942 Stalingrad became the third largest industrial town of the U.S.S.R. with a pop. (1939) of 445,476. It was the first of the great towns built under the first five-year plan, 1927; it had broad tree-lined streets, and produced tractors and other agricultural machinery, lorries, and motor cars—38,000 tractors in 1935, 60,000 in 1939. It had also oil refineries and sawmills, and during the Second Great War, until devastated by the Germans, was an important producer of tanks and military vehicles. The Stalingrad region had a silk growing industry. *See* Stalingrad, Battle of.

STALINGRAD: THE BATTLE OF, 1942-43

Irene Clephane, Associate Editor, The Second Great War

A detailed account of one of the most critical engagements of the Second Great War, which marked the turning point in the struggle between the forces of the U.S.S.R. and the invading armies of Germany. See also Russo-German Campaigns

In the spring of 1942 the Germans decided to go for the oil in the Caucasus and leave for the moment the capture of Moscow and Leningrad. To gain control of Caucasia it was necessary to isolate it by driving through to the Volga. A hold on that mighty river would also interrupt the chief remaining means of transport of oil and grain from S. to central and N. Russia. The spot on the Volga chosen by the Germans for attack was the most westerly of its lower basin, Stalingrad, the former Tsaritsyn, now grown to the third largest industrial town of the U.S.S.R., and a highly important source of Russian war material, particularly tanks and vehicles. Stalingrad was not fortified, and with a maximum width of 5 m., it straggles along the right bank of the river for some 30 m. By the end of July, 1942, the Germans had reached the Don from Voronezh to the Sea of Azov except in the angle at the elbow of the river where the Russians still held the right bank between Kletskaya and Kalach, thus covering the direct road to Stalingrad. Below the junction of the Donetz with the Don, the Germans were already advancing into Caucasia.

Stubborn fighting for Kletskaya and Kalach began in the last days of July, but even after the Germans forced the river to the S.E. of Kletskaya on Aug. 23, thus threatening Stalingrad from the N.W., the Russians continued to hold a bridgehead on the right bank. Lower down the Don, the Germans made a first precarious crossing at Tsimlyansk on July 25, and by Aug. 5 reached Kotelnikovo, where they threatened Stalingrad from the S.W. Russian resistance was fierce, but by the first week of Sept. the Germans had advanced from their S.W. position to threaten the city also from the W. At times the Germans attacked on

a wide front, at other times on a narrow sector in an effort to drive a wedge into the stubborn Russian defence. They heavily bombarded chosen points from the air, obliterating the buildings in them. They gained ground, but often lost it again to Russian counter-attacks.

By the middle of Sept. fighting had reached the outskirts of the city which, however, was still far from that fall Hitler had confidently predicted would be rapid. From Sept. 23 a Russian force began to make its presence felt to the N.W. between the Volga and the Don, initiating local attacks on the entrenched positions the Germans had dug to protect the N. flank of the army attacking Stalingrad. These positions ran along the W. bank of the Don from Voronezh to the neighbourhood of Kletskaya and then across the river and E. to the Volga. The W.-E. section was strengthened by concrete works and dug-in tanks. Defence of the whole line was in

dustrial establishments in the N.W. of the city; while ferocious street fighting continued in localised attacks and counter-attacks along the whole length of Stalingrad. Dive bombers, tanks, light and heavy field artillery, machine-guns, mortars, grenades, and the automatic heavy-calibre small arms of the infantry were used in fighting that was particularly violent at street crossings. There had been no such fighting in history before, though it was to be duplicated in the battles of 1944-45 when the Germans were defending German-occupied and their own cities against the Allies.

The Germans opened each of their attacks by concentrating air and artillery bombardment on a few hundred square yards. When most of the buildings in the sector had been reduced to rubble small groups of sub-machine-guns, supported by tanks, crept forward under cover of the ruins and attempted to establish themselves. Every standing stone building became a fortress; and when the Germans captured the ground floor, the Russians climbed to the first and second floors, established machine-guns on the roof, and drove the Germans in the street back on to counter-attacking Russian columns. Such battles sometimes lasted for days.

The object of the Germans was to thrust through to the Volga, which would make impossible the reinforcing and supplying of the city across the river from Russia's vast untouched eastern empire. Such reinforcements and supplies came in by night throughout the battle, and guns of the Volga naval flotilla helped in the defence, the backbone of which was artillery established on the E. bank of the river. But rain, and mud, reduced the fierceness of the fighting. A new German offensive on Oct. 14 was damped down. As the result of a third in the fourth week of the month the Germans claimed to have reached the river; if they did reach it, they were very quickly driven back. Both armies now faced a winter of peculiar difficulty. Floating ice on the Volga made it difficult in Nov. to get supplies to the hard-pressed defenders; the Germans had to bring men and material over a thousand miles of devastated territory. Though temps. were not so low as those the Germans had suffered farther N. the previous winter, the winds blowing uninterruptedly across the steppes were bitter and penetrating.

Stalingrad Battle, inside Stalingrad,

German artillery shelling a factory, used by Russians as a base for counter-attack

the hands of troops of German satellite countries — Hungarians near Voronezh, Italians to Kletskaya, and Rumanians from there to Stalingrad. The attacks made by the Russians on these positions were easily held, yet diverted forces from the main German purpose.

A speech made by Hitler on Sept. 30 proclaiming that Stalingrad would be taken was followed by intensified German attacks directed against the workers' settlements and the great in-

Stalingrad Battle. Sketch map of the industrial city of Stalingrad with its immediate environs. Here one of the key battles of the Second Great War raged September, 1942-January, 1943

Early in Nov. Hitler announced that his main objective had been achieved, that he would sacrifice no more lives in attacks, but would eliminate remaining resistance by bombardment. Fighting on a reduced scale continued, but there were no further violent German offensives. Russian small scale attacks on the Germans' defensive northern line continued through Oct. and Nov., but were not regarded by the Germans as serious. S. of Stalingrad, as well as inside it, the Russians had been pushed back on the river, and appeared to have no room to develop a serious attack. While the Germans were concentrating on the

reduction of Stalingrad, however, the Russians, some 35 m. upstream from Kletskaya, established a bridgehead at Serafimovich, against the Italians; S. of Stalingrad they succeeded also in greatly reinforcing their troops without German

knowledge. They also assembled new armies E. of the Don, ready to go into action when that river froze.

Marshal Zhukov, who co-ordinated a series of Russian offensive operations planned already in the summer and explained by Stalin to Churchill when he visited Moscow in Aug., 1942, attacked simultaneously N.W. and S. of Stalingrad on Nov. 19. By the 22nd one army, under Zhukov's immediate command, had advanced from Serafimovich and captured Kalach; a second under Col.-Gen. Vatutin had seized Abganerovo to the S.W. of Stalingrad. These advances cut the two rly. lines to the W. on which the Germans depended for supplies and reinforcements. A third army, under Col.-Gen. Rokossovsky, was attacking the fortified German positions N. of the city, and reached the outskirts of Stalingrad on Nov. 24.

By the beginning of Dec. von Paulus's German 6th army was surrounded and being pressed into an ever-diminishing space. The Germans began to send in supplies and bring out the wounded by air; and S. of Stalingrad, about Kotelnikovo, they assembled a powerful striking force under von Hoth which succeeded in driving back Vatutin's forces some 30 m. But the Russians counter-attacked on the flanks of the German corridor thus created; and by the end of the year von Hoth was in full retreat towards Rostov. Fresh successes to the W. by Zhukov and Rokossovsky cut off all further possibility of relief for Paulus's invested forces. Summoned to surrender on Jan. 8, 1943, Paulus refused. Intensification of the Russian attack split his forces into a number of groups which were pounded unmercifully by artillery at shorter and shorter range. On Jan. 27, by which time the remnants of the besieged German force had been squeezed into two pockets less than two miles deep, one in Stalingrad, one just to the N. of it, Rokossovsky's forces linked from the W. with the Stalingrad garrison under Gen.

Stalingrad Battle. Sword of Honour presented by George VI to the Russian people to mark British admiration for their valiant defence of Stalingrad

Stalingrad Battle. Archway erected on the west bank of the Volga to commemorate the limit to which the Russian defenders retreated

Roodimtsev, thus finally raising the siege of the city. Paulus, promoted F.-M. at the moment of his capture, and 24 generals were taken prisoner when the German h.q. in Stalingrad fell on Jan. 31. On Feb. 2 the group N. of the city was annihilated. In the final stand 195,000 Germans, the remains of an army that numbered 330,000 on Nov. 23, 1942, died or were taken prisoner.

The heroic defence of Stalingrad was the turning point of the war in Russia. The fanatical courage of the garrison could not have maintained it so long had it not been possible to bring in supplies and reinforcements across the Volga; and the conformation of the river banks—steep, and with ravines that could be used to shelter reserves and munitions—became increasingly important as the Russians were pushed back until eventually they held only a half-mile strip of the city along the river itself. The fact that the Russians did hold Stalingrad brought disaster to the German armies, which, first prevented from sweeping on through Caucasasia by the diversion of strength to the attack on Stalingrad, were in the end exhausted and driven into retreat. The admiration and gratitude of the West found a token expression in the sword of honour forged by order of King George VI on behalf of the British Empire and presented by Churchill to Stalin at Teheran in Dec., 1943.

Stalino. City of the Ukraine S.S.R., capital of Stalino region.

The former Yuzovka, it lies on the river Kalmus about 65 m. N.E. of Mariupol. On the Donetsk coalfield, it was before the Second Great War the most important industrial city of the Donetsk basin, with blast furnaces, rolling mills, and other installations. The Russians admitted its evacuation Oct. 26, 1941, after many days' heavy fighting against the Germans; with its liberation, Sept. 8, 1943, the expulsion of the Germans from the Donbas was completed. Pop. (1939) 462,000

Stalinsk. Town of the W. Siberian region of the R.S.F.S.R. The former Kuznetsk, it lies on the upper Tom river at the head of navigation 205 m. S.S.E. of Tomsk, with which it is connected by rly. A town of 3,890 in 1936, it had a pop. of 169,540 in 1939 with its development as the chief iron and steel centre in the Kuzbass (*q.v.*). Gold, precious stones, and other mineral products occur in the vicinity.

Stalk. Stem of a plant. (*See Botany; Plant.*) By analogy it is sometimes used for a stem of other kinds, *e.g.* a wine-glass. The same word, derived from an Anglo-Saxon root, also means to walk cautiously. One who pursues game in a stealthy way is called a stalker.

Stalky and Co. Book by Rudyard Kipling, composed of loosely connected short stories of school life. For both the school and the chief characters running through the stories the author drew on reminiscence of his

own schooldays. The school was the United Services College, then at Westward Ho!, N. Devon. The three chief characters, the occupants of "Study Number Five," were admitted portraits. "Stalky" was L. C. Dunsterville; "McTurk" was G. C. Beresford (who wrote *Schooldays* with Kipling, 1936, revealing how closely the stories were based upon fact); "Beetle" was Kipling himself. The book was published in 1899, but further Stalky stories were occasionally included in later books. *Consult* *An English School*, in Kipling's *Land and Sea Tales*, 1923.

Stall. Word with various meanings. One is for a division of a stable, in which a horse or other animal is placed. Another is for a bench or table, on which articles are exposed for sale in markets, and a third is for a certain class of seats in a theatre. The right of erecting stalls in market places is known as *stallage*.

In ecclesiastical architecture, a stall is an elevated seat in the choir or chancel of a cathedral or church. It is enclosed at the back and sides, high, projecting arms separating it from its neighbour. Rows of stalls for the use of clergy and choristers are usually arranged N. and S. of the choir. Extraordinary attention was lavished on the carving of stalls. There are 110 of them in Amiens cathedral, of carved oak, decorated with hundreds of figures, and the dark oak stalls of Henry VII's Chapel, Westminster Abbey, are noteworthy. The seat of a stall is hinged so that it can be folded against the back, and a device for the comfort of its

Stall. Part of Henry VII's Chapel, Westminster Abbey, showing the stalls of the Knights of the Bath, surmounted by their crests and banners; the lower seats are those of their squires

occupant is the Miserere (*q.v.*). Today the word is used in a figurative sense for the office of a canon residentiary in cathedrals and collegiate churches, *e.g.* Westminster Abbey. See Canon; Cathedral.

Stallion. Male horse kept for breeding purposes. The necessary characteristics of a stallion are size, substance, and a sound constitution. The best colours are brown, bay, or black. Another point is freedom from vice or nervousness, both these faults being hereditary in the horse. No one without a licence may keep a stallion of an age over that fixed by the minister of Agriculture unless it is a thoroughbred or a pony of a type prescribed by the minister, or was at least four years old when the Animals Act, 1948, came into force. See Horse.

Stalloy. Silicon-steel which has a low hysteresis loss. It is mainly used in transformers and similar electrical apparatus involving alternating magnetic fields.

Stalybridge. Mun. borough and market town of Cheshire, England. It stands on the Tame, which divides Cheshire from Lancashire, 7 m. E. of Manchester, and is served by rly. A trolley-bus service also connects the town with Manchester. The chief buildings

include the town hall and several churches. Mainly an industrial town of modern growth, Stalybridge has manufactures of cotton and calico goods and paper, engineering works, foundries, etc. It was made a bor. in 1857, and from 1867 to 1918 had its own M.P.; Stalybridge and Hyde is now the name of a co. constituency. Stalybridge owes its name to that of the family formerly owning the land and the fact of there being a bridge here. Its evolution from a small village began in 1776, when a cotton mill was built here. Market day, Mon. Pop. 24,831.

Stamen (Lat., a thread). Male organ of a flower, as the pistil is the female organ. There are usually several stamens, and may be many in each flower, and these are known collectively as the androecium. A stamen consists of a more or less slender stalk (the filament), and two anthers, which as a rule have two hollow lobes (thecae) united by the connective, which is a continuation of the filament. The thecae are filled with grains of pollen, which contain the male

gamete, and correspond to spores of ferns; the thecae split by definite lines or open by pores for the pollen to escape. If the filament is wanting, the anther is described as sessile; if attached by its entire length to the filament, it is adnate; if attached by its base only, it is innate; if the filament is connected to the middle of the back of the anther, the latter is said to be versatile. Where the stamens are aborted and have ceased to function as sex organs, they are known as staminodes. See Botany; Cell; Flower; Plant.

Stamford. Mun. borough and market town of Lincolnshire and Northamptonshire, England. It

stands on the Welland, 16 m. N.W. of Peterborough, with rly. stations. Of its existing buildings those of historical interest include churches of S. Mary and All Saints, both mainly of the 13th century, S. George and S. John the Baptist, both 14th century, and S. Martin, in which Lord Burghley (d. 1598) is buried. Browne's Hospital is a 15th century building, and other charitable foundations include the Burghley hospital and Snowden's almshouses. Besides a town hall, corn exchange, grammar school, and infirmary, there are remains of a Benedictine monastery founded in the 7th century, and the town had several other religious houses. The centre of an agricultural trade, Stamford has engineering works, breweries, and manufactures of wagons, farm implements, etc.

Stamford is said to have been the scene of a defeat of the Picts and Scots by Hengist in 449. One of the five boroughs of the Danes, it became a royal borough under Edward the Confessor and was soon a prosperous place. In the 12th century weaving was carried on, and there several fairs were held. The castle, which stood several sieges, was held by the Warenne family, 1206-1331. Stamford was made a corporate town in 1461. From 1295 to 1885

Stamford was separately represented in parliament; it now forms part of the co. constituency of Rutland and Stamford. Near the town is Burghley House, the town having been connected with the Cecil family since the 16th century. Market day, Fri. Pop. 10,910.

Stamford. City of Connecticut, U.S.A., in Fairfield co. It stands on Long Island Sound, 34 m. N.E. of New York, is served by the New York, New Haven, and Hartford rly., and is virtually a "dormitory" suburb of New York City. Industries include the manufacture of locks, typewriters, pianos, and hardware. Settled in 1641, Stamford was incorporated in 1830, and became a city in 1894. Pop. 47,938.

Stamford, EARL OF. English title held by the family of Grey since 1628. The earldom was granted to Henry Grey, grandson and heir of Sir Henry, 1st Baron Grey. The 1st earl of Stamford was lord-lieutenant of Leicestershire, and a prominent parliamentarian, his eldest son being one of the judges of Charles I. The 1st earl was succeeded by his grandson Thomas, son of the regicide, in 1673. Roger (b. 1896), who became 10th earl in 1910, was associated with public activities in Manchester, and was the first mayor of Altrincham in 1937-38.

Stamford Bridge, BATTLE OF. Fought between the Norwegians under Harald Hardrada, and the English under their king Harold, Sept. 25, 1066. At the instance of Harold's brother Tostig, the Norwegian king had invaded England, and had landed near York. Meanwhile Harold, who was also expecting a Norman invasion, was collect-

Stamford arms

Stalybridge arms

Stamford, Lincs. and Northants. Air view of the town, with S. Mary's Church in the foreground

ing his army in the south. On Sept. 24 he reached Tadcaster, while his enemies marched out to Stamford Bridge, in the E. Riding of Yorks, 9 m. N.E. of York.

Harold having in vain offered generous terms to Tostig, and seven feet of earth for a grave to the tall Norwegian king, the battle raged for a good part of the day. At last the English broke through the Norwegian front, and Hardrada was killed. Reinforced from their ships, the Norwegians almost turned the day, but in the end the English prevailed.

Stamfordham, ARTHUR JOHN BIGGE, BARON (1849-1931). British soldier and court official. Born June 18, 1849, the son of the vicar of Stamfordham, he entered the Royal Artillery in 1869. He saw active service in the Zulu War of 1878-79, after which he left the army to become a member of Queen Victoria's household. In 1895 he was promoted to be her private secretary, and knighted, and after her death he served the prince of Wales, afterwards George V, in a like capacity. When the prince came to the throne in 1910, Sir Arthur Bigge remained his private secretary, and in 1911 was made a peer. He died March 31, 1931, and the title became extinct.

Stamford Hill. London district, N. of the met. bor. of Hackney (*q.v.*), with Stoke Newington W., and the Essex border on the E. It contains Clapton Common, 7½ acres, acquired for the public in 1872; Springfield Park, 32½ acres, acquired in 1903; and the Skinners' Company's school for girls, 1890. At Stamford Hill the lord mayor and corporation of the City met James I on his way to London in 1603.

Stammering. Defect of speech in which there is inability to pronounce certain letters or combinations of letters, or a tendency to stumble over syllables, transpose letters, or rapidly repeat letters (stuttering). The actual cause is lack of coordination between the various parts concerned in speaking. Stammering may be manifested in early childhood, or may arise later in life as a result of severe nervous shock, in which case it is a symptom of hysteria. The symptom was frequently seen in soldiers suffering from shell-shock. The nervous factor in stammering is also shown by the fact that normal persons under the influence of strong emotions, such as fright or rage, may stammer temporarily. Treatment lies in eliminating any physical cause, such as enlarged

tonsils, which may be a centre of irritation. Reading aloud, systematic exercises of the voice by those trained in the subject, and patient effort nearly always result in cure. *See Deaf and Dumb; Voice.*

Stamp, JOSIAH CHARLES STAMP, 1ST BARON (1880-1941). British administrator and economist.

1st Baron Stamp, British economist

Stamp was born June 21, 1880, and entered the civil service in 1896, being appointed assistant secretary to the board of inland revenue in 1916. He left the government service in 1919 to become a director of Nobel's Industries, Ltd. In 1925 he became president of the executive, and later chairman, of the L.M.S. rly., and joined the directorate of the Bank of England in 1928. Apart from these business activities, he held at various times many university appointments in economics and political science, having great influence on financial and industrial developments after the First Great War. In July, 1939, Stamp became economic advisor to the govern-

ment and prepared a survey of the government's war plans. A man of outstanding probity, he was raised to the peerage in 1938, and was killed in his London home in an air raid during the night of April 16-17, 1941. His eldest son, Wilfred Carlyle (b. 1904), killed in the same raid but presumed to have survived his father, was 2nd baron; his second son, Trevor Charles (b. Feb. 13, 1907), reader in bacteriology in London university, succeeded as 3rd baron.

Stamp Act. Act requiring stamps of varying values to be affixed to legal documents. In Great Britain an Act was passed by parliament in 1765, as a means of raising new revenue. It was provided that the Act should apply to the American colonies, but this extension aroused the bitterest opposition in the colonies, on the ground that it contravened the fundamental principle of the Bill of Rights, *viz.* no taxation without representation. The colonial resistance to the Act was so strenuous that in 1766 it was repealed, though parliament endeavoured to save its dignity by passing at the same time a Declaratory Act asserting its right to tax the colonies. *See American Independence, War of.*

STAMP COLLECTING AND COLLECTORS

Douglas Armstrong, Editor of Stamp Collecting

Cognate articles are those on Book Collecting; Chinaware; Coins; Furniture; Medals; Numismatics; Pottery

Stamp collecting is today the most popular of all collecting pursuits. It is sometimes known by the semi-scientific term of philately. Stamps have been collected almost since their introduction by Great Britain in May, 1840. The hobby has made its greatest strides since the 1920s. Collectors of stamps are now numbered by the million and are found in every civilized community. In England alone they are catered for by about 3,000 stamp dealers, while many governments maintain philatelic agencies for supplying the latest issues, from which they derive substantial revenues. Pioneer collectors were Dr. Gray of the British Museum, Sir Daniel Cooper, Judge Philbrick, Rev. J. E. Stainforth, and Mount Brown, who compiled one of the earliest catalogues in 1862. An open-air stamp bourse flourished in Brechin Lane, London, in the early 1860s, and in 1866 the stamp trade was first recognized by the London directory. Famous among early stamp dealers were E. Stanley Gibbons, W. E. Lincoln, P. L. Pemberton, and

W. Whitfield King. Stamp albums began to appear in 1862, and in the same year the first periodical devoted to stamp collectors, the *Monthly Advertiser*, was published, at Liverpool.

In just over a hundred years some 88,000 different stamps have been issued all over the world, 18,000 within the British Commonwealth, and 70,000 by foreign countries, exclusive of "varieties." Their number is increased by approximately 2,000 new issues annually. Most early stamps carried portraits of reigning rulers or heraldic devices. Not until the 20th century were pictorial designs introduced, covering a wide range of subjects from art to zoology, so that there is now scarcely a phase of human interest not represented on postage stamps. Historical and national events are frequently commemorated with special issues of stamps, such as the silver jubilee of George V (1935), the coronation of George VI (1937), the centenary of the postage stamp (1940), victory in the Second Great War (1946),

and the silver wedding of the king and queen (1948). Stamps have also been used extensively to raise money for charitable objects, like the Red Cross, by selling at a small premium over their face, or postal values. Special stamps for exclusive use on airborne correspondence form a large and popular group. The most important stamp collection ever formed was that brought together by Baron von Ferrari; this was dispersed by auction in Paris during 1921-22. It contained practically all of the rarest specimens and realized nearly £200,000. Twenty years later it was worth probably twice that. As a result of the increasing number of collectors, and uncertain financial conditions, stamp values have risen rapidly and rare stamps are recognized as a sound investment. The most important collection of stamps of the British Commonwealth was started by George V, who was a very keen philatelist; this was later continued by George VI. Included are many unique items in the way of artists' original drawings, proofs, and essays, as well as the finest known example of the 2d. blue Mauritius stamp of 1847, purchased for £1,450 in 1904 and now worth more than £5,000. The rarest stamp in the world, the 1 cent British Guiana of 1856, of which only one example exists, is valued by its present owner, an American collector, at some £10,000. The most valuable British stamp is the 10s. Edward VII issue overprinted "I.R.OFFICIAL" for departmental use. In mint, i.e. unused, condition, it was in 1948 catalogued at £1,750.

Before 1945 the finest public stamp collection was that in the Berlin postal museum. Next to it ranks the Tapling collection in the British Museum, containing more than 100,000 stamps issued before 1900, many of them of great value, and is estimated to be worth quite £150,000. The national stamp collection of the U.S. is housed in the Smithsonian institute at Washington, and there are many other valuable collections in the U.S.A.

Public exhibitions of stamp collections on an international scale are held every few years in one or other of the capital cities. London was the centre in 1890, 1897, 1906, 1912, and 1923. Societies of stamp collectors for mutual pursuit of the hobby number nearly 250 in Great Britain alone. At the head is the Royal Philatelic Society, London, founded in 1869, with the king as patron. Stamp exchange clubs are also numerous. London is the world centre of the stamp trade. The Strand (London) and Nassau Street (New York) have the largest number of stamp shops. Organized bodies for the promotion and pro-

stamp lovers of Britain, America and most European countries.

Bibliography. Chats on Postage Stamps, F. J. Melville, 1913; A Key to Stamp Collecting, D. B. Armstrong, 1938; Stamp Collecting, S. Phillips, 3rd ed. 1942; Stamp Collecting, R. Curle, 1946; Famous Stamps, L. N. and M. Williams, new ed 1947; Collecting Stamps, D. B. Armstrong, new ed. 1947; British Stamps, P. Hamilton, 1948.

Stamp Duties. Duties collected by means of stamps, which are bought and affixed to documents. In the U.K. they are collected by the inland revenue department. Duties on playing cards, etc., are

properly stamp duties, but the term is usually confined to those charged on the transfer of land, mortgages, insurance policies, bills of exchange, contract notes, and other documents by which property is transferred or privileges secured. Early in the 17th century the Dutch began to raise money in this way and soon England followed the example. The proposal to impose stamp duties on the American colonies led to the War of Independence. See United States.

Stamp Mill. Machine used for the fine crushing of mineral ore. It has been developed from the pestle and mortar. The mortar is a cast-iron rectangular box provided with a feed slot at the back and screens in the front. Usually five stamps, consisting of heavy stems with a steel shoe at the bottom, work in each box. These stamps are raised by means of cams, and, falling by gravity, crush the ore on the steel dies placed in the bottom of the mortar box. Shoes and dies are renewable.

Water flows through the mortar box to carry the crushed ore through the screens. Other accessories are ore feeders, to keep a supply of ore on the dies, and amalgamating plates or strakes, for mills crushing gold ores. This type of mill has been largely superseded by the rotary type of crusher.

Stanchester. Site of a Romano-British villa in Somerset, England. Situate 700 yds. E. of the parish

Stamp Collecting. Some much prized specimens. 1. First postage stamp, Great Britain, May, 1840, penny black. 2. First colonial stamp, Mauritius Post Office, 1847, one penny, orange. 3. Rare shilling stamp of Canada, 1851, inscribed Twelve pence. 4. Three-cornered stamp from Cape of Good Hope, 1861, fourpenny blue. 5. Rare misprint, a fourpenny stamp of Western Australia, 1854, with inverted frame which makes the swan appear upside down

tection of philately are the British Philatelic Association, the Philatelic Traders' Society, and the American Stamp Dealers' Association. An international stamp bourse is held in London every year. Auction sales of postage stamps are conducted several times a week throughout the year, in London, and in provincial cities at frequent intervals. Their annual turnover has been estimated at close on a million pounds. The first stamp auction was organized by Sotheby's in 1872. The literature of stamp collecting is greater than that of any kindred pastime. Hundreds of books and thousands of periodicals in all languages have been published on the subject. A philatelic library bequeathed to the British Museum by the late earl of Crawford, in 1913, contained some 15,000 items, and was by no means complete. Weekly, fortnightly, monthly, and quarterly journals are published for the

church of Curry Rivell, it has yielded coins of Trajan, Antoninus Pius, and later emperors, Samian potsherds, bronze bits, etc.

Stanchion. Pillar, post, or strut supporting a load. A stanchion may consist of a single section, such as a rolled steel joist or angle, or may be a number of sections. Stanchions supporting very heavy loads are usually built up of rolled steel sections, riveted together or connected by bars or plates. *See* Strut.

Standard. Literally, that which stands. The word is used for a flag or other ensign of war, and also for shrubs and trees not supported by a wall, *e.g.* a standard rose. In another sense it means an established model or rule, *e.g.* a standard of living, or a uniform system of measurement (*see* Standardisation).

The royal standard or personal flag of the British sovereign measures 15 ft. by 7½ ft., and is em-

Standard. The British Royal Standard, comprising the arms of England, Scotland, and Ireland

blazoned with the royal arms in their proper colours. It must only be flown when the sovereign is present, or by his viceroys and the governors and lieutenant-governors of colonies and possessions. The queen consort, queen dowager, and other members of the royal family have a personal banner.

The standard borne by the household cavalry and by regiments of dragoon guards in the British army is of crimson silk damask, embroidered and fringed with gold, the tassels and cords of crimson and gold mixed. The lance, including the royal crest, is 8 ft. 6 ins. long. The flag is 2 ft. 5½ ins., without the fringe, and 2 ft. 2 ins. on the lance; the corners are square, and it bears the badge, devices, and mottoes conferred by royal authority for services in the field. *See* Colours; Eagle; Flag.

Standard, THE. Former London daily newspaper. It was established by Charles Baldwin in 1827 as a Tory evening paper. In 1904 the property was bought by C. A. Pearson. In 1916 the goodwill and copyright of the morning edition were offered for sale by auction, but withdrawn; publica-

tion was suspended after March 16, 1916. *See* Evening Standard, The.

Standard, BATTLE OF THE. Fought near Northallerton, Yorkshire, between the English and the Scots, Aug. 22, 1138. Under David I the Scots invaded England to support the cause of Matilda against Stephen. The archbishop of York and the bishop of Durham took the lead in collecting an army, which gathered around the banners of S. Cuthbert of Durham, S. Peter of York, S. John of Beverley, and S. Wilfred of Ripon. These were all fastened together on a pole and surmounted by a cross, thus giving to the battle its name. The English won.

Standard Bread. A bread made of flour containing 80 p.c. of the whole grain. An effort was made by the Daily Mail in 1911 to standardise the quality of the flour used for bread-making, whence the name for this particular form of bread. Standard bread was a light fawn in colour, and contained the whole grain less 20 p.c. of husks. *See* Bread.

Standard Cell. Cell used as a practical standard for the measurement of electro-motive forces. Such cells must be of a permanent nature, ensuring constancy of E.M.F. and also its variation with temperature. The two cells mostly used are the Weston and the Clark cells, the former being employed for preference owing to its smaller temperature coefficient. On no

became an important, if unspectacular, function of the central government. The metric system is a powerful and flexible instrument for standardised measurement, and is in general use among scientists, along with the British foot-pound-second system where this is particularly applicable. The standardisation of fundamental measurements is an important step in the development of science; and modern industry owes much to those who, like Lord Kelvin, invented instruments by which standardised measuring and testing became possible.

It is standardised measurement that makes possible standardised components and standardised qualities of components, *e.g.* the threads on screws. It would be impossible to overestimate the importance to engineering of the work done by Whitworth in Great Britain and Sellers in the U.S.A. in the standardisation of screw-threads: assimilation of the two systems was agreed in 1948. Standardisation of components covers bolts and nuts, wire, rivets, pipes, steel rods, girders, rails, electrical sockets, etc.

Each standardisation is itself a highly technical enterprise, which can be undertaken only by a committee of experts representative of the manufacturers and the users of the thing that is being considered. The committee issues a specification which may from

Name	Positive Pole	Electrolyte	Negative Pole	Depolariser	E.M.F. (volts)
Clark . . .	Mercury	Saturated ZnSO ₄	Zinc Amalgam	Hg ₂ SO ₄ and ZnSO ₄	1.4328 at 15°C
Weston	Mercury	Saturated CdSO ₄	Cadmium Amalgam	Hg ₂ SO ₄ and CdSO ₄	1.0183 at 20°C

Standard Cell. Comparison of the Clark and the Weston cells

account must such cells be connected as generators in a low-resistance circuit.

Standardisation. In industry, commerce, and science, the process by which uniformity of type, quality, size, shape, method, or statement is secured, to ensure greater exactness and certainty, and to avoid waste of all kinds.

The first phase of standardisation arose in the measurement of time, length, and weight. Some degree of standardisation of these existed in the ancient Egyptian and Sumerian civilizations. Throughout the Middle Ages attempts were made to standardise the measurement of cloth, etc. As industry and trade progressed, so the number of standard measures grew. Their maintenance

time to time be amended in the light of experience.

The standardisation of components may lead to the standardisation of fitments, *e.g.* electric switches, locks, and to the standardisation of methods of using things. For example, a "code of practice" was issued for the gas industry, stating what are believed by an expert committee of technologists to be the best ways of installing gas service pipes, gas lighting, hot-water supply by gas, gas-operated refrigerators, etc.

The chief agency of standardisation in this country is the British Standards Institution, which grew out of the earlier engineering standards committee and was incorporated by royal

charter in 1920. Its authoritative committees cover most of the industries of the country. It has issued some thousands of standard specifications, an index of which is contained in its year book. It is a non-profit-making concern, deriving its income from the sale of its specifications and from grants from the industries it serves. The B.S.I. maintains close relations with similar institutions in other countries. Its own standard specifications have a world-wide circulation and use.

Such specifications make it possible to express contracts with both brevity and precision, since it is necessary only to quote a B.S. number instead of describing the commodity or process in detail. They facilitate economy in manufacture by eliminating unnecessary duplication of types, and thus permitting mass production. They lessen the amount of stock that needs to be carried by traders.

Standardisation such as that organized through the B.S.I. does not involve standardisation of taste. It is based wholly on technological considerations. Individual manufacturers, however, tend more and more to standardise their products in order to secure the utmost advantage of mass production. Such standardisation calls for the highest skill in industrial design and production engineering, for mass production requires large-scale investments in machine-tools, etc.

Much standardisation of contracts, procedures, etc., has been organized by professional men, merchants associated in the produce exchanges, etc.

Standardisation of equipment played an important part in the cooperation of the Allied forces during the Second Great War, and is necessarily the subject of careful consideration in any defence plans relating to the future. See Sample; Units; Weights and Measures.

Standard of Living. Concept in economics, meaning the sum total of the goods and services available to an individual or a family or a social class. Strictly speaking, no two individuals have an identical standard of living. Standard of living is sometimes referred to as standard of life, standard of comfort, and real income or real wages (in contrast to money income and money wages, the value of which fluctuates with prices).

One's standard of living concerns things and services purchased

directly, *e.g.* accommodation, clothes, food, fuel, water-supply, entertainment, travel; things provided communally, and purchased to some extent indirectly through the payment of rates and taxes, *e.g.* protection, education, use of roads, parks, libraries, art galleries; and things available freely through one's location, *e.g.* sunshine, sea-breezes, or sea-bathing, enjoyment of scenery, etc. During the 20th century a very large proportion of the things constituting the ordinary person's standard of living has been provided communally.

An individual's standard of living is much affected by his capacity to get satisfaction from what is available, *i.e.* it is in large measure the result of his physical and psychological condition. Education, by changing that condition, may materially influence the standard of living that can accrue from a certain money income.

It can be misleading to relate standard of living too closely to money income, or to speak of the standard of living of an occupational group, *e.g.* farm workers, coal-miners; but the money incomes of such groups at different times are frequently compared, after adjustments have been made for price changes, to yield a rough indication of change in the standard of living. Thus, if at one time the average wage of farm workers is £1 5s. and at another time £4 5s., and if in the meantime prices have risen $1\frac{1}{2}$ times, so that £2 10s. will purchase only as much as could previously be bought for £1, the later standard of living (real wages) is roughly $\frac{4\frac{1}{2}}{1\frac{1}{2}} \times \frac{1}{2} \times 100$ p.c., *i.e.* 136 p.c.

of what it previously was. Too much reliance should not be placed on such comparisons, as they ignore many factors, and assume too great an ability to measure generally changes of prices. A more reliable indicator of changed standards of living could be obtained from the comparison of statistics of housing, consumption of food, clothes, electricity, transport, etc., and of deaths, births, marriages, diseases, etc., though such a comparison would be difficult.

Following the rapid rise of prices during the First Great War an attempt was made by the ministry of Labour in 1915 to furnish a basis for the adjustment of wages to compensate for price changes by the calculation of a

so-called "cost-of-living index number." After the Second Great War this was replaced by an interim index of retail prices. See Cost of Living; Sliding Scale. Consult Principles of Economics, A. Marshall, 1890; Economics of Welfare, A. C. Pigou, 1920; National Income and Outlay, C. G. Clark, 1937.

Standard Oil Companies.

American commercial organizations. For some years up to 1911 there existed a wide international combine known as the Standard Oil company of New Jersey. It possessed virtual monopolistic control. In 1911 the U.S. supreme court held that the company offended against the Sherman Anti-Trust Act, and dissolved it. The associated oil companies were thus separated into their component parts, becoming competitors and thus fulfilling the objects of the law. The chief Standard Oil companies are those of New Jersey, California, Ohio, New York, Indiana, Louisiana, and Pennsylvania. Other companies remaining from the split are the Atlanta Refining company, the Prairie Oil and Gas company, and the Vacuum Oil company. The largest is the New Jersey company, with a share capital of \$1,500,000,000. The break-up of the original Standard Oil company was the culmination of a prolonged political and legal battle, and of great legal importance as a standing precedent for future action against trusts.

Standard Temperature and Pressure (S.T.P.). The standard conditions under which volumes of gases are compared. These conditions are a temp. of 0° C. and a pressure of 76 cms. of mercury. An alternative term is normal temp. and pressure (N.T.P.).

Standard Time. Method of making time uniform over a given area. The units are belts or zones, 15° in width, because time changes one hour for each 15°. In each belt time is regarded as uniform, changes of one hour being made when another belt is entered. The corresponding system at sea is called zone time. See Time.

In the U.S.A. a system of standard times for different regions, in use on the 15s. since 1883, was established by Act of Congress in 1918. The country is divided into four zones: Eastern, Central, Mountain, Pacific. Each is approx. 15° of longitude in width. Their boundaries are decided by an interstate commerce commission. The time in these

zones is slower than Greenwich time by five, six, seven, and eight hrs. respectively. In Alaska there is a special standard time, ten hrs. slower than Greenwich.

Standerton. Town of the Transvaal, S. Africa. It stands on the Vaal river, here crossed by five bridges, at an alt. of 5,000 ft., 110 m. S.E. of Pretoria, with which there is rly. connexion. An agricultural centre, it is the chief town of the E. Transvaal. There are English and Dutch churches. Here the government started an experimental farm, and in the dist. cattle, sheep, and horses are bred. Named after a Boer, Adrian Stander, the place was made a municipality in 1903. On June 22, 1900, it was occupied by British forces. Pop. approx. 10,800.

Standing Order. In British parliamentary procedure, a resolution of either house made for the guidance and order of proceedings. Such orders regulate the procedure on bills, the sittings of committees, and other matters, and remain in force until repealed by the house. Many resolutions regarding procedure have become customary, and are thus equivalent in effect to standing orders. (See Parliament.) This is also a military term for permanent orders listed for the ordinary administration of a camp or barracks.

Standish. Dist. of Lancashire, England, forming part of the urban dist. of Standish with Langtree. It is 3 m. by rly. N. of Wigan. The main industry is coal mining, and rayon is made and food processed. The chief buildings are the church and Standish Hall where the family of Standish lived some 800 years into the 20th century. There are an ancient cross and stocks. Pop. 8,743.

Standish, MYLES OR MILES (c. 1584-1656). One of the Pilgrim Fathers. Born at Duxbury, Lanes, he sailed in the Mayflower for Plymouth, Mass., where the first New England colony was founded. Owing to his experience in the Netherlands, Standish was appointed commander of the Pilgrims, and successfully conducted several campaigns against the Indians. He died at Duxbury, Mass., Oct. 3, 1656. The subject of Longfellow's poem *The Courtship of Miles*

Myles Standish,
Pilgrim Father

Standish is the marriage of Priscilla Mullens to John Alden, who had endeavoured to secure her hand for Standish. *Consult* Lives, J. Abbott, 1898; T. Jenks, 1905.

Standpipe. Open-ended vertical pipe on the delivery of a pump. The column of water in the pipe prevents sudden rises in pressure by increasing its height during a delivery stroke. The top of the pipe must be above the highest point to which the water is pumped. *See* Hydrant; Pump.

Stane Street. Early English name for a Roman road in Sussex and Surrey. Traceable from Chichester for 9 m. straight to Bignor Hill, after some meandering it runs straight again for 18 m. from Hardham to Minnick Wood. Hence it passes through Dorking, Epsom, Clapham to Newington Causeway. *See* Britain and map, p. 1442; *consult also* The Stane Street, H. Belloc, 1913.

Stanfield, WILLIAM CLARKSON (1794-1867). British painter. Born at Sunderland, he was a sailor until 1818, and then became employed on scene painting in Edinburgh, and at the Royalty, Coburg, and Drury Lane theatres in London. The marine subjects he subsequently produced are fresh and true to nature, but somewhat monotonously cold in colour. They include Mount St. Michael, 1830; Portsmouth Harbour (by royal commission), 1832; Battle of Trafalgar, 1836. Elected A.R.A., 1832, and R.A., 1835, he died at Hampstead, May 18, 1867.

Stanford, SIR CHARLES VILLIERS (1852-1924). Irish musician. Born in Dublin, Sept. 30, 1852, he was a choral scholar of Queens' College, Cambridge, and made his reputation as organist of Trinity College, 1873-92. From visits to Germany he brought back classical works to receive their first performances in England. As teacher of composition at the R.C.M. from 1883 he was unsurpassed. He held the chair of music at Cambridge from 1887 until his death on March 29, 1924; conducted the Bach choir, 1885-1902;

Sir Charles Stanford,
Irish musician
Russell

and directed the Leeds festivals, 1901-10. In 1902 he was knighted. No class of composition was untouched by the versatility of Stanford, and if he sometimes shows skill rather than depth, it can be said that his Anglican church music was the most satisfying for at least a century; his settings of Newbolt's nautical poems, for solo singer or chorus, are wholly individual; the clarinet concerto, Irish symphony in F minor (1887), and five Irish rhapsodies for orchestra are firmly in the repertory. His most successful opera was *Shamus O'Brien*, 1896; *The Canterbury Pilgrims* was given in 1884, *The Travelling Companion* posthumously, 1926. There are *Lives* by J. F. Porte, 1921; H. P. Greene, 1935.

Stanford, LELAND (1824-93). American capitalist. Born at Watervliet, N.Y., March 9, 1824. he went to Wisconsin in 1849 and practised as a lawyer. Stanford's business career started in 1856 at San Francisco, and some years later he came to the front as a rly. magnate, and also as governor of California. He was a senator in 1884, and again in 1890, dying June 20, 1893. In memory of his son, he founded Leland Stanford Junior University (*q.v.*).

Leland Stanford,
American capitalist

Stanhope. Urban dist. of Durham, England. It stands on the Wear, 25 m. N.W. of Darlington, and has a rly. station. The chief industries are connected with the lead, ironstone, and limestone quarries. The church dates largely from the 13th century. The living, one of the richest in England, has been held by several men who attained eminence, including Bishop Butler. In 1813, in some caves near here, the home and belongings of a family of the Bronze Age were discovered.

Stanhope, EARL. British title borne since 1718 by the family of the same name. This family, named from Stanhope in Durham, produced several famous men. Philip Stanhope, 1st earl of Chesterfield (d. 1656), had a younger son, Alexander, who was the father of James Stanhope, soldier and statesman, who in 1718 was made an earl. He receives a separate entry, as do the 3rd, and the 5th earls. The family seat is Chevening Park, Kent,

and an eldest son is called Viscount Mahon. (See Chesterfield, Earl of.)

James Richard Stanhope, 7th earl, was born Nov. 11, 1880, went to Eton and Magdalen College, Oxford, joined the Grenadier Guards, and succeeded to his father's title in 1905. After holding several junior offices he entered the cabinet in 1936 as first commissioner of works. He was transferred next year to the board of education, was first lord of the Admiralty 1938-39, and in Chamberlain's war administration was lord president of the council. During 1938-40 he was Conservative leader of the house of lords.

Stanhope, JAMES STANHOPE, 1ST EARL (1673-1721). English statesman and soldier. Born in

1st Earl of Stanhope,
English statesman

Paris, he was a grandson of the 1st earl of Chesterfield. Educated at Eton and Trinity College, Oxford, he became a soldier and served in Italy and Spain. In 1706 he was made minister at Madrid, and while the War of the Spanish Succession was raging he acted as both diplomatist and soldier. In 1708 he was chosen commander-in-chief, taking Port Mahon, but after some considerable successes he was defeated by the French in 1710 at Brihuega and taken prisoner. In 1701 Stanhope had entered parliament, and when he returned from Spain in 1712 he became prominent as a Whig politician. Having helped to bring about the accession of George I, he was made a secretary of state in 1714. As first lord of the treasury in 1718 he effected the Quadruple Alliance with France, Austria, and Holland. He died after an apopleptic fit, Feb. 5, 1721.

Stanhope, CHARLES STANHOPE, 3RD EARL (1753-1816). British politician and inventor. Born in London, Aug. 3, 1753, son of Philip, 2nd Earl Stanhope, and educated at Eton and Geneva, he early developed scientific tastes. He took out various patents for steam vessels, and invented printing processes and instruments, including a method of stereotyping, and

3rd Earl Stanhope,
British politician
After C. Warren

a press known as the Stanhope press. He also evolved tuning instruments, a microscope lens, and calculating machines. After six years in the commons, Stanhope succeeded to the peerage, 1786, and became prominent for his revolutionary activities. He was chairman of the Revolution Society, 1788, and so consistently opposed the war with France that he was known as "Citizen Stanhope." He died at Chevening, Kent, Dec. 15, 1816. See Printing.

Stanhope, PHILIP HENRY STANHOPE, 5TH EARL (1805-75). British historian. Born Jan. 30, 1805, he graduated from Christ Church, Oxford, in 1827, and entered parliament in 1830. Until his succession to the title in 1855 he was styled Viscount Mahon. An unwavering opponent of the Reform Bill of 1832, in 1842 he was instrumental in amending the law of copyright. His historical works are largely derived from rare sources. History of the War of Succession in Spain, 1702-14 (1832), was followed by History of England from the Peace of Utrecht to the Peace of Versailles, 1713-83 (1836-53). His Life of William Pitt, 1861-62, is a standard work. He died Dec. 24, 1875.

Stanhope, LADY HESTER LUCY (1776-1839). English traveller. Born at Chevening, Kent, March

Lady Hester
Stanhope
After W. Wright

12, 1776, she was the eldest daughter of the 3rd Earl Stanhope. She went in 1803 to keep house for her uncle, William Pitt, over whom she acquired a remarkable ascendancy. On his death in 1806 she received a pension of £1,200 a year, but finding private life insupportable she left England in 1810 with a small entourage, and by 1813 had settled among the Druses, in a lonely villa about 8 miles from Sidon, on Mt. Lebanon, in Syria. There she lived until her death, June 23, 1839, in a quasi-Oriental style, surrounded by obsequious servants and exercising a sort of dominion over the neighbouring tribes. *Consult* Memoirs, 1845; Travels, C. L. Meryon, 1846; Life, J. Haship, 1934.

Stanhope Medal. British civil award. It is presented by the Royal Humane society for the bravest deed of attempted lifesaving of the year, either afloat or ashore. The medal is gold and bears on the obverse the effigy of a boy blowing on an extinguished torch to illustrate the accompanying motto: *Lateat scintillula forsan* (perhaps a little spark may yet lie hid). The reverse carries a civic wreath and the inscription *Hoc pretium cive servato tulit* (he obtained this award for saving a citizen). When it is presented for an unsuccessful attempt to save a life, the inscription is altered to *Vita periculo exposita dono dedit societas regia humana* (the Royal Humane Society presented this to—who exposed his life to danger). As a civil decoration, the medal is worn on the right breast, and is suspended from a light blue ribbon with outer stripes of dark blue and inner stripes of yellow. It is attached to the ribbon by a bar inscribed Stanhope Medal.

Stanislas I (1677-1766). King of Poland. Born at Lemberg (Lvov), Oct. 20, 1677, the son of

Stanislas I,
King of Poland

R a p h a e l Leszczynski, he was made palatine of Posen by Augustus II. When Charles XII of Sweden declared war against Poland, Stanislas was elected a representative at the congress of Warsaw, 1704. Charles supported his claims to the throne, and he was crowned, Oct. 7, 1705. He was forced to flee to Bessarabia in 1712. In 1725 Louis XV of France married Mary, Stanislas's daughter, and supported his claim to the Polish throne. Russia, however, besieged Stanislas in Danzig (1734), and, French help being late and insufficient, Danzig capitulated. By the treaty of Vienna, 1738, he renounced the throne of Poland, although permitted to keep the title of king. He was compensated with the duchies of Bar and Lorraine. Stanislas wrote *Oeuvres du Philosophe Bienfaisant*, 1764, and died Feb. 23, 1766.

Stanislas II (1732-98). King of Poland, born Jan. 17, 1732. A son of Stanislas Poniatowski, he became attached to the English embassy in St. Petersburg, where he was one of the lovers of the empress Catherine. In 1764 she secured his election as king of Po-

land. His reign saw the inauguration of economic reforms, but he was powerless to resist the partitions of his country. Stanislas was compelled to abdicate in 1794, and his last years were spent in prison in St. Petersburg, where he died Feb. 12, 1798.

Stanislavov (Pol. Stanislawow, Ger. Stanislaw). Town of Ukraine S.S.R. It lies near the Bistrizta, in a fertile plain, 75 m. S.E. of Lvov. During 1915-17, when it lay in Austrian Poland, it was the scene of conflicts between Austrians and Russians. In the area conquered by Poland, 1919-20, it was in Russian-occupied Poland after the Russo-German partition of 1939, was lost to Germany, 1941, recaptured July 27, 1944, and ceded to Russia under the Russo-Polish treaty of Aug., 1945. It made machinery and leather goods, and had a trade in flour, grain, and tobacco. The town gives its name to an administrative region. Pop. approx. 60,000.

Stanislavsky, CONSTANTIN (1863-1938). Russian theatrical director. Constantine Sergeevich Alexeev was born in Moscow, Jan. 18, 1863, went early on the stage, and produced plays for a society of art and literature. With Danchenko in 1898 he founded the Moscow Art Theatre, the opening production being *The Seagull*. A pioneer in the methods of modern "group" production, he made naturalism in his theatre of paramount importance. Rehearsals sometimes lasted a year. While he acted with success, his reputation rested on his genius as a director. After the Revolution, when the theatre was influenced by Communist doctrine, Stanislavsky in 1922 took his company on a two years' tour of European capitals. He was awarded the order of the Red Banner in 1933, and died Aug. 7, 1938. The 4th ed. of his autobiography, Eng. trans. J. J. Robbins, appeared in 1947.

Stanley. Urban dist. of Durham, England. It stands in a colliery district, 8 m. N.W. of the city of Durham. Pop. approx. 50,000.

Stanley. Urban dist. of Yorkshire (W.R.), England. It is 3 m. N. of Wakefield, and has a rly. station. It stands in a colliery district and has manufactures of rope and bricks. Pop. 16,090.

Stanley. Seaport of Tasmania. It is situated on the N. coast in the municipality of Circular Head, and has connexion by motor and rly. (167 m.), and by steamer with Launceston, and by steamer with Melbourne and Sydney. Pop. 620.

Stanley. Only town and administrative centre of the Falkland Islands. It is on the E. of E. Falkland, and has a good harbour, which was once a naval station. There are a wireless station and a government school. Pop. 1,246. See Falkland Islands.

Stanley. Name of a famous English family of which the earl of Derby (q.v.) is head. It took its name from Stanley in Staffordshire, the original name having been Aldithley or Audley. The Stanleys moved to Cheshire, settling in Wirral, and there Sir John (d. 1414) made the family fortune by marrying a Lancashire heiress, Isobel Latham. Through her he obtained Knowsley, still the residence of the earls of Derby, and much of the land on which Liverpool now stands. Sir John was given the lordship of the Isle of Man by Henry IV. His grandson Thomas was made Lord Stanley in 1456. The latter's son Thomas (d. 1504) became earl of Derby in 1485, after helping his son-in-law, Henry VII, to win the battle of Bosworth. From the elder Thomas is also descended the branch now represented by Lord Sheffield, who holds the barony of Stanley of Alderley created in 1839. A barony of Stanley, which had been in abeyance since 1594, was revived in 1921 in favour of the countess of Loudoun. Stanley was also the surname of Lord Ashfield (q.v.).

Stanley, ARTHUR PENRHYN (1815-81). British divine. Born at Alderley, Cheshire, Dec. 13,

Arthur P. Stanley.
British divine

1815, the son of a future bishop of Norwich, he was educated at Rugby and Balliol College, Oxford, where his scholarship won distinction. A fellow of University College, he was ordained in 1839 and took a leading part in university life. In 1851 he was made a canon of Canterbury, and in 1856 professor of ecclesiastical history at Oxford. He travelled considerably, and in 1862 accompanied the prince of Wales to Palestine. From 1864 Stanley was dean of Westminster. In 1863 he married Lady Augusta Bruce (1822-76), daughter of the earl of Elgin, and he died July 18, 1881.

As an author, Stanley is best known by his *Lectures on the History of the Jewish Church*, 1863-76. He also wrote a *Life of*

Thomas Arnold, 1844; *Memorials of Canterbury*, 1855; *Sinai and Palestine*, 1856; *Memorials of Westminster Abbey*, 1865. His broad church views made him conspicuous; he was found favouring all liberal movements in theology and all efforts to open the Church of England to men of diverse views. *Consult* *Life and Correspondence*, R. E. Prothero and G. G. Bradley, 1893; A Victorian Dean, ed. H. Bolitho, 1930.

Stanley, SIR HENRY MORTON (1841-1904). British explorer. Born at Denbigh, June 29, 1841,

he was the son of John Rowlands, a grazier; his youth was passed in extreme poverty, and in 1859 he ran away to Liverpool and sailed to New Orleans,

Henry Morton Stanley

where he was adopted by a cotton broker named Stanley. In 1861 he joined the Confederate army and was taken prisoner next year at Shiloh. Then he transferred to the Federal artillery, was discharged on account of ill-health, served a spell in the navy, and drifted into journalism. In 1868 he accompanied Napier's expedition to Magdala as representative of the *New York Herald*.

The next year saw him embark on his life's work. Livingstone had been lost near Tanganyika, and Gordon Bennett, proprietor of the *Herald*, commissioned Stanley to find him. Stanley started from Zanzibar in 1871 with 3 white men, 31 native soldiers, and 153 carriers, and on Nov. 3 at Ujiji he greeted the lost explorer with the words, "Dr. Livingstone, I presume?" After three months Stanley returned alone to Europe and published *How I Found Livingstone*. In 1873 Stanley accompanied Wolseley's Ashanti expedition, which he described in *Coomassie and Magdala*, 1874, and then he set out on his second journey to Central Africa, sponsored jointly by the *Daily Telegraph* and the *New York Herald*. He occupied three years in crossing the continent, and not until Aug., 1877, did he reach Boma with a few survivors of his party. Through the *Dark Continent*, 1878, recounted his adventures.

Leopold II of Belgium persuaded Stanley to undertake a further

exploration of the Congo, whither he returned in 1879 to spend five years. Returning to Europe, he was entrusted in 1887 with the expedition to relieve Emin Pasha, who had been cut off in Equatorial Africa by a Mahdist rising. After some remarkable marches he succeeded in his main object, though some 400 of his company died; and discovered Ruwenzori and Lake Edward Nyanza.

Stanley returned to England, was naturalised, brought out in Darkest Africa, 1890, and sat as Liberal Unionist M.P. for N. Lambeth, 1895-1900. A final journey elicited his last book, *Through South Africa*, 1898. He was made G.C.B. in 1899, married Dorothy Tennant next year, and died May 10, 1904. Courageous, humane, and a brilliant organizer, he ranks with the greatest explorers. He was portrayed by Spencer Tracy in the film *Stanley and Livingstone*, 1939.

Bibliography. Autobiography, ed. by his widow, 1909; *Life and Travels*, H. W. Little, 1890; *With Stanley's Rear Guard*, H. Ward, 1891; *H.M.S., Explorer*, J. Wassermann, Eng. trans. 1932; *Life*, F. Hird, 1935; *The Remarkable Expedition*, Olivia Stanley, 1947.

Stanley, OLIVER FREDERICK GEORGE (b. 1896). A British politician. A son of the 17th earl

Oliver Stanley,
British politician

of Derby, he was educated at Eton and Oxford and was called to the bar in 1919, after serving with distinction in the First Great War. He entered parlia-

ment in 1924 as Conservative member for Westmorland, which he represented for 21 years. From 1945 he sat for W. Bristol. He was minister of Transport, 1933; of Labour, 1934, in which year he became a privy councillor; president of the board of education, 1935; of the board of trade, 1937. Early in 1940 Stanley succeeded L. Hore-Belisha at the War office, being replaced by Anthony Eden in May. His last post in the coalition government was at the Colonial office, 1942-45. In opposition he developed an incisive and witty debating manner.

Stanley, WENDELL MEREDITH (b. 1904). American biochemist. He was educated at Earlham College and Illinois university, and during 1930-31 held a research post in Munich. Returning to

America, he held positions at California, Harvard, Cornell, and Princeton universities during 1936-42, and did valuable research on the purification and isolation of enzymes and virus proteins, being eventually in charge of research on these subjects at the Rockefeller Institute, Princeton. In 1946 he and J. H. Northrop (*q.v.*) were jointly awarded half the Nobel prize for chemistry.

Stanley Pool. Lake expansion of the river Congo. About 25 m. long by 16 m. wide, it is situated N.E. of Léopoldville at the beginning of the longest navigable stretch of the river. It was discovered by Stanley in 1877.

Stanleyville. Town on the river Congo. It is situated at the farthest navigable point for steamers ascending the river from Léopoldville before the rapids, Stanley Falls, between Stanleyville and Ponthierville are reached. It is about 800 m. direct N.E. of Léopoldville, and is connected by rly. with Ponthierville, 78 m., where the Congo again becomes navigable. Stanleyville is the capital of the eastern prov. of the Belgian Congo.

Stannmore OR STANMORE MAGNA. Part of the urban district of Harrow, Middlesex, England. It is 13 m. N.W. of Euston by rly., and is a terminus of the Bakerloo line. A fast-growing residential district, Stanmore is pleasantly placed on the slopes of a hill which reaches 480 ft. and is crowned by Stanmore common. At Stanmore in the Second Great War were the h.q. of Fighter Command. Near the parish church of S. John the Evangelist, cons 1850, are the ruins of a church dating from 1632. Bentley Priory, named after a priory of Austin canons, has historical and literary associations.

Stannard, HENRIETTA ELIZA VAUGHAN (1856-1911). British novelist, who wrote under the pen-name John Strange Winter (*q.v.*).

Stannaries (Lat. *stannum*, tin). Term used for tin mines, especially those of Cornwall and Devon. For hundreds of years the tin mines of that region had their own laws, customs, and organization. They had a meeting on Hingston Down, and later had their own representative assembly, or parliament, wherein laws were passed. This met for the last time at Truro in 1752. The district had its courts, which dealt with matters affecting the mines, but this jurisdiction was transferred to the county court in 1896. See Cornwall; consult *The Stannaries*, G. R. Lewis, 1908.

Stannic Acid. One of the tin compounds. It exists in two forms, both solid, distinguished as stannic and metastannic acids, or as alpha- and beta-stannic acids. Stannic acid (H_2SnO_3) is prepared by adding calcium carbonate to a solution of stannic chloride. It forms a series of salts known as stannates. Meta-stannic ($H_2Sn_5O_{11}$) acid is obtained by the action of nitric acid on tin (*q.v.*).

Stannite. A complex sulphide of tin, copper, and iron. It is also known as tin pyrites, or bell metal ore. Stannite is found in small amounts in many tin deposits, but only in Bolivia does it constitute an important ore mineral of tin.

Stanovoi. Mountain range, or rather plateau, of E. Siberia. It is considered by some part of, by others separate from, the Yablonoi system on the W. It forms the watershed between the rivers that flow into the Arctic Ocean and the Pacific, and extends about 2,400 m. between the Amur river and Bering Strait.

Stans OR STANZ. Town of Switzerland, capital of Nidwalden. Situated at an elevation of 1,495 ft., 2 m. by rly. from Stansstad, its port on Lake Lucerne, it contains a Capucin monastery. Pop. 3,000.

Stansfeld, SIR JAMES (1820-98). British politician. Born in Halifax, Oct. 5, 1820, and educated at

University College, London, he became known as a speaker at Radical meetings. In 1859 he entered parliament as Liberal member for Halifax, and in 1863 he was made a lord of the Admiralty. A friend of Mazzini, he was while in office accused by the French govt. of complicity in plots against Napoleon III. Stansfeld resigned, but returned in 1866 as under-secretary for India, and in 1869 he was made financial secretary to the treasury, and in 1871 president of the poor law board. In 1872 he became the first president of the new local government board he had helped to set up. He was out of office from 1874, except for a few weeks in 1886, but remained in parliament until 1895. He was a prime mover from 1874 in the agitation which led to the repeal of the Contagious Diseases Acts (*q.v.*) in 1886. He died Feb. 17, 1898. His *Life* was written by J. L. and B. Hammond, 1932.

Sir James Stansfeld,
British politician

Stansgate, WILLIAM WEDGWOOD BENN, 1ST VISCOUNT (b. 1877). British politician. Born

Viscount Stansgate,
British politician

May 10, 1877, and educated at London university, he was Liberal M.P. for St. George's, Tower Hamlets, 1906-18, then for Leith until 1927. Having joined the Labour party, he was secretary for India, 1929-31, while representing N. Aberdeen, and he sat for Gorton, Manchester, from 1937 until raised to the peerage in 1941. Wedgwood Benn served as an airman in the First Great War, rose to air commodore, and in 1945-46 was in charge of the Air ministry. He had been the vice-president of the Allied control commission for Italy after her withdrawal from the Second Great War.

Stanton Drew. Village of Somerset, England. It is 7 m. S. of Bristol, and there are coal mines in the neighbourhood. It is famous for its stone circles, the largest being 168 ft. in diameter. These are probably Druidical.

Stanton Drew, Somerset. Stone circle, probably of Druidical origin

Stanza. Division of a poem. In regular metrical verse there will be a given number of lines arranged in a pattern, as regards syllabification, rhyming, etc., to form one stanza; and each stanza of the poem will probably have the same arrangement. Thus Gray's *Elegy* may be described as being in 32 four-line stanzas. *Strophe* is an alternative term, mostly applied to classical verse.

Stapeldon, WALTER DE (1261-1326). English divine, born Feb. 1, 1261, at Annery, Devon. Educated at Oxford, where he

Walter de Stapeldon,
British divine

held the chair of canon law, Stapeldon was elected bishop of Exeter, 1307. He devoted much energy and wealth to rebuilding the cathedral. In conjunction with his brother, Sir Richard, a judge, he founded Stapeldon Hall, Oxford (now Exeter College), for poor scholars from his diocese. Appointed high treasurer in 1319, he became unpopular as a close associate of Edward II, and was murdered by a mob in Cheapside, Oct. 15, 1326. See Screen illus.

Staphylococcus (Gr. *staphylon*, bunch of grapes; *kokkos*, berry). Micro-organism which receives its name from its appearance under the microscope. The cause of boils, carbuncles, etc., it may be kept in check by penicillin and the sulphate of drugs.

Staple (A.S. *stapul*). Word used in a number of senses. In engineering, it is a loop of iron or a piece of wire bent and provided with two points to drive into wood to hold a hook or pin. A similarly shaped piece of wire is used as a paper fastener. In mining, a staple is a shaft to join different levels.

Staple (O. Fr. *estaple*, mart; Low German *stapel*, heap or storehouse of wares). Originally a mart

foreign merchants who used their privileges to such purpose that outcry was raised from time to time by English traders. In 1353, under Edward III, was passed the Statute of the Staple, which, after providing that all staple goods should be brought to a staple town in England, declared that "they shall be exported by merchant strangers only, and not by the king's subjects, who are to take an oath not to hold any staple beyond seas." Moreover, the courts set up in the staple towns to settle disputes between buyers and sellers were made up of two Englishmen and four aliens, and this provision gave the foreigner yet another advantage over English competitors. See *Free Trade*; *Hanseatic League*; *Protection*; consult *The Germans in England*, I. D. Colvin, 1915.

Stapleford. Part of the urban dist. of Beeston and Stapleford, Notts, England. It stands on the Erewash, 6 m. W.S.W. of Nottingham, and is served by rly. It has a beautiful old church and a fine Anglo-Saxon cross. Lace is manufactured. Pop. 8,838. Another Stapleford is near Hertford, and was scheduled as a new town after the Second Great War, but the project was abandoned on investigation.

Staple Inn. Surviving relic of old London. It is on the S. side of Holborn, W.C., facing Gray's Inn Road. In ancient times a commercial centre, associated with wool staplers, whence its name, it was one of the inns of chancery from the time of Henry V until 1884, when it was purchased by the Prudential Assurance co. The front was restored 1886 to its original design, and the other buildings were reconstructed in 1937, only to be heavily damaged by a flying-bomb on Aug. 29, 1944. There is a Dutch garden. The hall, dating from 1581, with a hammer-beam roof, is let to the Institute of Actuaries. Johnson wrote *Rasselas* at a house in Staple Inn, which is described in Dickens's *Edwin Drood*. See *Holborn*; *Inns of Court*; consult also *Staple Inn and Its Story*, T. C. Worsfold, 1913.

Star, THE. London evening newspaper. Established by T. P. O'Connor (q.v.), Jan. 17, 1888, its circulation eventually reached more than a million daily. Independently radical, it specialises in outspoken leaders and features on social topics, its picture service, and its sport. "T. P.", editor during 1890-93, was succeeded by H. W. Massingham (q.v.). A. L. Cranfield became editor in 1941.

Star and Garter, THE. Name of a hotel which once stood on Richmond Hill, Surrey. The original building was set up by John Christopher in 1738. Rebuilt before 1780, it was taken, 1809, by Christopher Creak, once cook to the duke of York, and in 1822 passed to Joseph Ellis, under whom it became famous.

In 1858 the property was taken over by a company and a palatial structure erected. The terraced gardens were laid out in Italian style. The hotel figures in *Vanity Fair*. It was pulled down in 1919 to make room for a home for paralysed and permanently disabled ex-servicemen, opened 1924 by King George V and Queen Mary. See Richmond.

Star Apple (*Chrysophyllum cainito*). Evergreen tree of the family Sapotaceae, native of the

Star Apple. Spray of leaves and clustered flowers; right, fruit

West Indies. Its branches are clothed with rusty down, and the juice is milky. It has alternate, oblong leaves, covered with rusty hairs on the underside, and small white flowers. The edible fruit, like a large apple, is yellowish-green tinted with rose. When cut across the soft sweet flesh is seen to be divided into ten cells, each containing a seed.

Staraya Russa. Town of the R.S.F.S.R., in the region of Leninograd. It is on the slopes of the Valdai Hills, and is 36 m. S. of the city of Novgorod, and formerly possessed an imperial palace and a cathedral dating from 1701. Captured by the Germans about Aug. 20, 1941, Staraya Russa was the scene of fierce fighting and of the encirclement of their 16th army by the Russians during Feb., 1942.

This siege, however, was raised on April 24, and Staraya Russa subsequently became an important German base. It was liberated by the Russians, Feb. 18, 1944. Pop. 21,500.

Stara Zagora or **ESKI ZAGRA.** Town and co. of Bulgaria, in E. Rumelia. Situated on the S. slope

Star and Garter, Richmond. Air view of the Star and Garter home for disabled ex-servicemen, opened 1924

of the Balkans, it is about 50 m. N.E. of Plovdiv, with which, and with Burgas, on the Black Sea, it is connected by rail. It is a prosperous commercial centre, with manufactures of carpets, and is famous for its otto of roses. The co. has an area of 6,002 sq. m. and a pop. of 812,633. Town pop., 29,825.

Starboard. Right-hand side of a ship or aircraft, looking forward. Being on the starboard tack means having the wind on the right-hand side of a vessel. See Navigation; Port Side; Ship.

Star Catalogue. List of stars giving such data as their accurate positions in the heavens. The first catalogue of the stars was that of Hipparchus, formed 127 B.C., and contained just over 1,000 stars. In A.D. 138 Ptolemy produced the *Almagest*, in which were catalogues of stars in the N. and S. hemispheres, probably a revision of the catalogue of Hipparchus.

The more modern catalogues began with the appearance of the great comet of 1832, which attracted the attention of many photographers. Celestial photography was developed by the brothers Henry in Paris, and by them the first successful photographic refracting telescope was made. From this period dates the astrographic catalogue of the whole of the heavens, inaugurated in 1887 by a number of the world's observatories and in 1948 still in course of completion. See Stars.

Starch (M.E. *sterche*, stiffen). Constituent of plants which is both important and widely distributed. It is formed in the tissues by the action of chlorophyll under

the influence of light and is stored by the plant as a food reserve in stems (e.g., sago), tubers (e.g. potatoes), fruits (e.g. bananas), etc. Transfer to these storage reservoirs is effected by breaking down the starch in the leaves and green parts to sugars which pass through the cell walls and are reconverted to starch in the storage cells. The starch is thus available for use by the plant until it is sufficiently mature to produce starch itself.

The starch consists of oval-shaped grains built up of layers round a nucleus or hilum. The size varies from 0.004 to 0.14 mm. and under the microscope the size, shape, and arrangement around the hilum are distinctive and characteristic of the plant of origin.

Chemically the starches are polysaccharides—carbohydrates having the empirical formula $(C_6H_{10}O_5)_n$; the value of n is not known, but is more than 4. On heating with dilute acid starch is hydrolysed to sugars, dextrose, maltose, and glucose being the chief. Hydrolysis is effected in the plant by enzymes. This process is taken advantage of in the fermentation industries, the enzyme diastase being the active constituent of malt.

On heating to about 320° F. starch is converted to dextrin (British gum), a yellow powder soluble in water and much used as an adhesive.

MANUFACTURE. The process of manufacture is simple in the case of such materials as potatoes, which are comparatively free from gluten. The potatoes are disintegrated and washed with cold water on a sieve which permits the starch granules to pass, but retains the pulp. The starch granules settle, and fibres and impurities are washed away. After further washing the starch is dried, the final water content being about 17 p.c.

In rice the gluten is rendered soluble by treatment with dilute caustic soda. Wheat is reduced to a dough, the starch being separated by a roller that presses it through a fine screen from which it is removed by a water spray. Hard granules contain two polysaccharides, 10 p.c.—20 p.c. of amylose, which is soluble at 60°, and 80 p.c.—90 p.c. amylopectin, which forms starch paste with hot water. The gelatinising temp. of starch varies from 145° F. (potato) to 158° F. (sago).

Starch is used in industry for sizing yarn and cloth and thickening mordants and dye solutions in calico printing. In the laundry

trade it is used as a finishing agent. Large quantities of starch, chiefly potato starch, are used in the preparation of adhesives of the dextrin type. Various starches are used in the preparation of food stuffs and confectionery, particularly cornflour, arrowroot, tapioca, and sago; and in the natural state the starchy foods, e.g. potatoes, rice, constitute an essential part of the diet (see Carbohydrates).

T. Hedley Barry

Star Chamber, THE. English law court constituted by statute in 1487. It was used by Henry VII as an instrument for checking powerful nobles whose influence might exercise undue pressure upon the ordinary courts of law. The creation of this new body was a formal assertion of privileges of jurisdiction long claimed by the privy council, the officers of state who acted as judges being drawn from that body; and at first the star chamber was a beneficial body. Under the Stuarts, however, it became distinguished for its tyrannical procedure and the savage penalties it inflicted. It was abolished by Act of parliament in 1641. See Privy Council.

Starfish. Popular name for the class Asteroidea of the echinoderms, in which the body is ex-

posed of small suckers by means of which the animal crawls slowly along. The skeleton consists of small rods and plates of chalky material. The alimentary canal consists of a sac in the centre of the body, communicating with the mouth beneath and with a minute anus above. The food consists chiefly of marine bivalve molluscs, which the starfish gradually pulls open. It is very destructive to oyster and mussel beds. See Animal colour plate; Echinodermata.

Stargard (Pol. Starogard). A town of Pomerania in the part of Germany placed under Polish rule in 1945. It is on the Ihna, which is here navigable. 22 m. S.E. of Szczecin (Stettin). The Gothic church of S. Mary dates from the 14th and 15th centuries, and there is a 16th century Rathaus. Parts of the old town walls with gateways and towers remain. Stargard became a town in 1229, and was a member of the Hanseatic League. Pop. (1939) 32,545.

Starhemberg, ERNST RUEDIGER, PRINCE OF (b. 1899). Austrian politician. Born May 10, 1899, at Eferding, Upper Austria, descendant of a famous aristocratic family, he studied law at Innsbruck and Munich, served in the First Great War, fought against the Poles in Upper Silesia, 1920, and became leader of the unofficial home defence force (*Heimatschutz*) Upper Austria in 1928 and in all Austria in 1930. He was minister of the interior. Sept.-Dec., 1930, and vice-chancellor under Dollfuss 1934-35, and Schuschnigg, 1935-36, and leader of the anti-Nazi, anti-Socialist "fatherland front" until Nov., 1936. Forced to resign then, and emigrating when the Nazis invaded Austria in 1938, he served for a short time with the R.A.F., 1939-40, then as a French lieutenant, before disappearing to Argentina for the rest of the war. There he wrote a book, *Between Hitler and Mussolini*, and established claims upon liberated Austria, e.g. for the restitution of 13 Starhemberg castles and estates.

Stark, FREYA MADELINE. British explorer. Educated in Italy, at Bedford College, and the School of Oriental Studies, she travelled widely in Persia and the Middle East, and during the Second Great War served the ministry of Information in Aden, Cairo, Bagdad, and later in Canada and the U.S. Her travels were described in a series of books, including *Bagdad Sketches*, 1933; *The Valleys of the Assassins*, 1934; *The Southern Gates of Arabia*, 1936; *Seen in the Hadhra-*

maut, 1938; *Letters from Syria*, 1942; *East is West*, 1945; *Perseus in the Wind*, 1948. Her autobiography, *Traveller's Prelude*, was published in 1950.

Stark, HAROLD RAYNSFORD (b. 1880). U.S. naval officer. Born at Wilkes-Barre, Pennsylvania, Nov. 12, 1880, he was educated at the U.S. naval academy, and was commissioned in 1905. In the First Great War he served as aide to Admiral Sims, then held positions of increasing importance with the U.S. Fleet. From 1942 to 1945 Admiral Stark was commander of the U.S. naval forces in Europe. In 1943 he had much to do with the achievement of temporary agreement in N. Africa between the two generals, de Gaulle and Giraud.

Stark, JAMES (1794-1859). British artist. Born at Norwich, Nov. 19, 1794, he studied under John

Crome and at the R.A. schools. Although his art was hampered by ill-health, he became one of the most prominent painters of the Norwich group, painting woodland, river, and

James Stark,
British artist

coast scenery. His early life was passed in or near Norwich, but about 1839 he removed to Windsor, and in 1849 to London, where he died, March 24, 1859.

Stark, JOHANNES (b. 1874). German physicist. Born 15 April, 1874, at Schickenhof, Bavaria, Stark became professor of physics at the technical university of Hanover in 1906, Aix-la-Chapelle in 1909, at the university of Greifswald 1917, at that of Würzburg 1920, retiring in 1922 and going to live near Munich until 1933, when he was appointed president of the Physikalisch-technische Reichsanstalt at Berlin. A pioneer of theoretical atom physics, Stark discovered optical effects in 1905 and in 1913, those of the latter discovery being called after him, and gaining for him the Nobel prize for physics in 1919. His own theory concerning the nature of atoms was based upon what he termed "the axial effect of the emission of light" (1927), and his writings were mostly concerned with the spectra of atoms. As an active member of the Nazi party, connected with the German atomic experiments for war purposes, he appeared before a denazification court after the Second

Starfish. Five Fingers, *Asterias rubens*, the common starfish; top, Palms of placenta, or Bird's foot

tended into a series of rays or lobes producing the conventional star-shape. There are numerous species, distributed throughout the world, and several are common about the British coasts. The rays are in no sense limbs or tentacles. The mouth is situated in the centre of the underside of the body, and the rays are covered beneath with rows

Great War and was sentenced to four years in a labour camp.

Starley, JAMES (1831-81). British inventor. Born at Albourne, Sussex, April 21, 1831, the son of a farmer, Starley made his way to London in 1846, and while acting as a gardener devoted his attention to improving various mechanical devices round him. He joined a sewing-machine firm in 1855, and brought out a sewing-machine of his own invention in 1857. He turned his attention in 1868 to bicycles, and by the large number of his ingenious inventions, he succeeded in making Coventry, where he had settled, the centre of the bicycle trade. He died at Coventry, June 17, 1881. His nephew, John Kemp Starley, having entered the business, followed up these inventions and is regarded as the inventor of the safety bicycle, which was first shown at a cycle club show in Jan., 1885. *See* Bicycle.

Starling (*Sturnus vulgaris*). Name applied to numerous birds, but particularly to the common

Starling. Insectivorous bird, common in large flocks throughout Britain and Europe

W. S. Berridge, F.Z.S.

starling of Europe, a familiar British bird. It is about eight inches long, and has black plumage with green and purple reflections, the upper feathers being tipped with buff and the under tail coverts edged with white. The female has the plumage spotted below as well as above. Though not famed as a songster, the starling is remarkable for the variety of the notes that it utters, which often suggest imitations of fragments of the song of other birds. It is mainly insectivorous in diet, and spends much of its time on the ground probing for worms and grubs. The nest is composed of grass, twigs, and moss, and is placed in a hole in a tree or old building, or under the eaves of a house, and is used year after year. Starlings occur in large flocks,

which migrate from one district to another when food becomes scarce. *See* Bird; Eggs col. plate: Pastor.

Star of Bethlehem (*Ornithogalum umbellatum*). Bulbous herb of the family Liliaceae, a native of Europe. The scaly bulb is about an inch across, and the long, narrow leaves have a white stripe down the centre. The flower-stem branches above and bears from six to ten white flowers, an inch and a half across. The name is given to

Star of Bethlehem. White-striped, grass-like leaves, and clustered flowers of the bulbous herb

the star which guided the wise men to Bethlehem (Matt. 2).

STARS: THEIR NATURE & MOTIONS

* A. Hunter, Ph.D., F.R.A.S., Royal Greenwich Observatory

This Encyclopedia contains articles on the chief stars and constellations, e.g. Arcturus; Leo; Sirius. See also Astronomy and Astrophysics; Nebula; Planet; Sun; also Telescope, and the biographies of Copernicus; Galileo; Herschel; Lowell, P.; and other leading astronomers

The stars are heavenly bodies of a nature similar to the sun, intensely hot self-luminous globes, of dimensions far superior to the earth. The especial prominence of the sun is due to the fact that the earth is a member of its system; the other stars are isolated from us by vast distances. By analogy we may suppose that they are the centres of similar systems of planets. Some observational evidence of this for two of the nearer stars was obtained in 1943.

About 6,000 stars are sufficiently bright to be seen with the naked eye. The most powerful telescopes, aided by the photographic plate, reveal objects at least a million times fainter and the number of stars rises to thousands of millions. It is believed that further increase of light-grasp will not increase the total indefinitely, and that there is a definite system of the stars, limited in numbers and extent (*see* Galaxy). Other isolated systems still more remote in space exist in the extra-galactic nebulae (*q.v.*).

The configuration of the stars in the sky has not noticeably altered in historic times, but accurate measurements show that the positions are not absolutely fixed. In most cases a small displacement known as the star's proper motion can be detected. Of the bright northern stars Arcturus has an exceptionally rapid motion of 2.3 seconds per year; it was this star especially which led Halley to discover these movements in 1718. The motion of Arcturus is surpassed by that of a number of faint stars, the largest known being 10.3 seconds per year for a telescopic star in the constellation Ophiuchus discovered by Barnard in 1916. With this motion it would travel over the diameter of the full moon in 180

years. In most cases, the movements are very much smaller.

In general the nearest stars are likely to show the greatest apparent displacements, and much information of a statistical kind as to the distances and distribution of the stars has been obtained from a study of these motions. A very remarkable advance in our knowledge has been gained by the application of the spectroscope (*q.v.*) to measure the rate at which a star is approaching or receding from the earth. This radial velocity could not be found otherwise, since it makes no difference in the star's apparent position in the sky; moreover, the spectroscopic determination gives the speed in miles per second instead of in angular measure. The method depends on measuring the positions of the dark lines which appear in the spectra of stars; it is known that these must be displaced towards the violet or red end of the spectrum (*q.v.*) according as the star is approaching or receding. After a long period of unsuccessful attempts to apply this principle, practicable methods have been developed and great accuracy of measurement is now attained (*see* Doppler's Principle).

The Sun's Motion

By a study of the motions it has been found that the sun, carrying with it the earth and planets, is moving at a speed of 12 m. a second towards a point not far from the star Vega. This is the sun's proper motion and is quite normal for a star of its nature. Superposed on this motion is one of rotation, at about 160 m. per second, around the centre of the galaxy, some 30,000 light years away in the direction of the constellation of Sagittarius.

Not all proper motions are random; some examples of organized motion have been found, especially the "moving clusters" or groups of stars, often widely separated in the sky, which move with precisely equal speeds in parallel courses. A system consisting of five stars of the Great Bear with Sirius and some other rather bright stars is a good example of such a group.

For a few of the stars it is possible to measure the distances by a direct method known as parallax (*q.v.*) determination. The nearest known star is the bright southern star α Centauri, its distance being 25,000,000,000,000 m. This seems to be about the average distance which separates one star from its nearest neighbour. Other bright stars within a distance not more than three times as great are Sirius and Procyon. But, generally speaking, the brightness of a star is no clue to its distance.

If we could view all the stars from one standard distance, we should find a great diversity of brightness. There are some stars giving out 10,000 times as much light as the sun; others give only 1/10,000th of its light. The sun is about average in brightness.

It is possible in certain cases to "weigh" the stars, and it is found that they all consist of much the same amount of material; there must be very few stars indeed with masses outside the limits $\frac{1}{2}$ and 10 times that of the sun. The brightness depends mainly on the physical state; some stars have higher surface-temperatures than others, and consequently are more luminous; many of the stars are extremely diffuse globes having densities less than that of air.

Spectroscopic Observation

The nature of some of the substances contained in the stars can be ascertained by the spectroscope; in almost all cases the materials are identified as familiar terrestrial elements. The stars have been classified into various groups according to the spectra which they show. The presence or absence of the spectrum of a particular element must not, however, be taken to denote abundance or lack of that element; it is rather an indication of the temperature and other physical conditions, since special circumstances besides the abundance of the element are necessary to render a particular spectrum conspicuous. The spectral classes are therefore believed to denote, not fundamental differences of constitution, but different physical states of a star. There is a

recognized succession of these classes (called by the letters B, A, F, G, K, M), which is also the order of decreasing surface-temperature, from about 30,000° C. to 3,000° C.

The B stars are all intrinsically bright, but a cool red M star may be either a "giant" (about as bright as a B star) or a "dwarf" some 10,000 times fainter. The diameters of the stars can be inferred from their temperatures and luminosities. The red giants, which are highly luminous in spite of their low temperatures, must achieve this by radiating from very large surfaces. Betelgeuse, for example, has a diameter about 300 times that of the sun. On the other hand, the white dwarfs are faint stars despite their high surface temperatures: they must therefore be very small. The companion to Sirius has a diameter only 1/10,000th that of the sun. Since the masses of these stars do not differ by a factor of more than 15, it follows that their densities must differ enormously, from high-vacuum conditions in Betelgeuse to 40,000 times that of water in the white dwarfs.

Theoretical considerations indicate that the internal temperatures of the stars are very high: about 20,000,000° C. at the centre of a star like the sun. The stars are caused to shine for millions of years by the release of nuclear energy from the atoms subjected to these enormous temperatures.

Study of Double Stars

Many of the stars which appear single to the naked eye are found with the telescope to be double. In the great majority of cases the two components are found to be really associated and to share the same motion. By taking advantage of this knowledge it has been possible in some cases to "weigh" the two components. The period of revolution ranges from six years upwards. Even when a star is seen as a single point with the telescope, it is often found by the spectroscope to be alternately receding and approaching in regular cycle; it is fair to conclude that it must be revolving round another body of great mass. Thus many more double stars are revealed. These have comparatively short periods, sometimes less than a day, and the two bodies are separated by a space usually much less than the distance of the earth from the sun. Probably more than one-third of the whole number of stars are double.

Many stars vary periodically in brightness; these fall into at least three groups. (1) About 800 *Algol*

variables are known, which are simply double stars, in which the fainter component partially hides its companion once in each revolution, and so causes a decrease of light by eclipse. The best known example is *Algol*, which suffers an eclipse lasting nine hours every 3 $\frac{1}{2}$ days. (2) The *long-period variables* have a somewhat rough periodicity usually between 200 and 600 days. These show a much more marked fluctuation of light than the other classes. It seems that a great conflagration breaks out cyclically, so that the star gives 100 or 1,000 times more light than when quiescent. The variation seems to be inherent in the physical condition of the star, and may perhaps be analogous to the outbreak of spots on the sun which follows an 11-year cycle. (3) The *Cepheid variables* undergo a quick cycle of change, the period being a few days or a few hours. The change of brightness is small, and seems to be due to a regular pulsation of the star, the temperature falling and rising as it expands and contracts.

Notwithstanding the great variety of conditions in the stars and the vast distances between them, they must be regarded as units in one great process of evolution, and as associated in one great stellar system. This system has a flattened shape something like a lens, and the star clouds forming the Milky Way are coiled round in the same plane. It is possible that the whole system resembles one of the spiral nebulae which have been discovered in great numbers by methods of stellar photography.

Bibliography. *Stellar Movements and the Structure of the Universe*, A. S. Eddington, 1914; *Astronomy*, vol. 2, H. N. Russell, R. S. Dugan, and J. Q. Stewart, 1927; *General Astronomy*, H. S. Jones, 1934; *Atoms, Stars, and Nebulae*, L. Goldberg and L. H. Aller, 1941; *The Story of Variable Stars*, L. Campbell and L. Jacchia, 1946.

Stars and Bars. The flag of the Confederacy in the American Civil War. It consisted of three bars of red, white, and red, in a blue canton containing white stars to the number of the seceding states, arranged in a circle.

Stars and Stripes. Popular name for the flag of the United States of America, also known as "Old Glory." Hence The Star-Spangled Banner (*q.v.*), now the national anthem of the U.S.A. It is now composed of seven horizontal red stripes and six horizontal white stripes (which represent the original 13 states seceding

from the British crown), and a blue canton with 48 stars, in six rows of eight stars. In June, 1777, the flag had only 13 stars, but it was later

Stars and Stripes, the flag of the United States of America

decreed that a star should be added for every new state admitted to the Union. In the first type 12 stars were arranged in a circle with the 13th placed in the middle. In 1818 they were grouped to form a large star of five points. Then they were placed in rows, to form diagonal lines, but in 1819 the horizontal and perpendicular alignment was adopted. See United States.

Star Shell. Artillery projectile used for illuminating positions at night or for signalling. The shell

Star Shell. Sectional diagram showing filling. See text

is similar in construction to that used for shrapnel, but instead of a destructive filling contains a cardboard or varnished paper cylinder filled with a mixture of powdered magnesium and barium nitrate, and attached to a folded parachute. The diagram illustrates the most common type. The shell body, A, has a loose base, B, held in position by pins, C, above which is a split steel cylinder surrounding the folded parachute, K, which supports the star, G, in the case, F, by means of the shackle, J. The open end of the case contains a priming composition in which are set igniting pellets with strands of quickmatch. A perforated bridge above the star supports the bursting charge of gunpowder, E. The fuse, D, ignites the burster, which fires the quick match and ejects the star through the shell-base, when the parachute is withdrawn, opens, and slowly falls with the burning star.

Star shells were extensively used in the trench operations of the First Great War, and by ships on patrol, but in the more mobile land fighting of the Second Great War they were superseded by the more effective parachute flare dropped from aircraft. See Flare; Illuminating Shell; Rocket.

Star-Spangled Banner, THE. National anthem of the U.S.A., officially adopted as such in 1931. During the war in 1814, Francis Scott Key, a Baltimore lawyer, solicited under a flag of truce the release of a friend captured by the British. As an attack by the English fleet upon Fort Mifflin was then pending, Key was temporarily detained during the night. The attack failed, and in the morning the Stars and Stripes still waved above the fort. Moved by patriotic fervour, Key wrote some verses, afterwards published in The Baltimore American.

Its unusual metre was no doubt adopted on account of the popularity of an air to which several patriotic songs had already been fitted in America, viz. To Anacreon in Heaven, composed about 1771 by John Stafford Smith for the Anacreontic Society, a convivial club which met at a London tavern. Attempts to claim the tune as of American origin were overthrown by Oscar Sonneck in his monograph on the subject written for the library of congress. See National Anthem.

Starter. Mechanism fitted to an internal combustion engine for starting it. The self-starter takes the form of an electric motor supplied with current from the accumulator or battery of the vehicle when the starter switch is closed. The drive from the motor shaft is by a pinion which is automatically brought into mesh with a ring of gear

teeth formed on the periphery of the engine flywheel. When the engine starts the pinion is automatically disengaged from the flywheel teeth. Engagement and disengagement of the pinion are brought about by mounting it on a screw thread on the motor shaft, so that it can move axially along the shaft. On pressing the starter switch the motor begins to spin, but the inertia of the pinion causes it to lag behind, and so move along the shaft, engaging the flywheel. When the engine fires, the greater rotational speed imparted to the pinion by the flywheel causes it to move axially along the shaft out of engagement.

Aircraft piston engines are commonly started by electric motors as are other I.C. engines. Alternatives are the inertia and the cartridge starter. In the former a small free flywheel, electrically energised, on reaching high r.p.m. is engaged with the engine crankshaft through a clutch and gearing. Cartridge starters in large or small aircraft engines (and on marine and stationary Diesel engines) are

Star-Spangled Banner. Music for the voice part of the national anthem of the U.S.A.

By courtesy of Novello & Co., Ltd.

in the form of a revolver breech, loaded with cartridges resembling those for a sporting shot-gun. On firing by remote control from the cockpit the charge is ignited and the gas pressure depresses a small piston in the mechanism which, via a helical coupling, turns a starter shaft which is dogged to the main crankshaft.

For aircraft gas turbines, owing to the high inertia of the rotating unit and the need for a long period of acceleration up to about 3,000 shaft r.p.m., large electric motors are generally used, the engagement, disengagement, fuel injection, and ignition all being part of an automatic starting cycle.

Starting Handle. Detachable cranked handle for imparting initial rotation to an internal combustion engine by manual means. The ratcheted teeth on its shaft are made to engage with corresponding teeth on the forward end of the crankshaft, and a clockwise motion is imparted until the engine fires, when the handle is at once forced out of engagement. See Internal Combustion Engine.

Starvation (A.S. *steorfan*, to die; *sterfan*, to kill). State of exhaustion due to prolonged lack of food. It may also occur in animals supplied with improper forms of food which they cannot assimilate. In infants, emaciation follows, and rickets or scurvy may develop. Partial starvation is used by physicians as a method of treatment in some conditions, either to rest the gut or in cases of diabetes or obesity. Diseases which interfere with the taking or assimilation of food, such as cancer of the gullet, lead to death from starvation. Abrupt and complete deprivation of food, as in entombed miners, leads to death much more rapidly than the gradual deprivation of food. If both food and water are withheld, life is not likely to be prolonged for more than 8 or 10 days. If water is available, life may be maintained for six weeks, and longer periods are recorded. In a person deprived of nutriment, the craving for food passes off in a few days, but pain and sensations of distress are felt in the epigastrium. Emaciation and weakness supervene. The chemical processes of the body are completely altered, with the formation of poisonous substances. The temperature may be sub-normal. Hallucinations and delirium precede death. See Diet; Hunger-strike.

Stassfurt. Town in the Magdeburg dist. of the *Land* of Saxony-

Anhalt, E. Germany. It stands on the Bode, 20 m. S. of Magdeburg. The principal building is S. John's church, a 16th century building. The chief industry is mining for salt, the town having extensive mines of rock salt, and the richest deposits of kainite (potassium and magnesium sulphate) in the world. Stassfurt existed in the Middle Ages, and was once a fortified town. Pop. (with the connected town of Leopoldshall) 30,000.

Statant (Lat. *stare*, to stand). In heraldry, an animal standing in profile is said to be statant, unless of the deer tribe, when it is described as "at gaze." See Heraldry colour plate.

State. Modern name for the body politic, "a people organized for law within a definite territory." The word means literally a *standing*, something set up or established; that something is the body in which is vested the force of the community, so that it can be "organized for law." Within its territory the state must be free from external control, i.e. it must have sovereignty within its boundaries.

A state is not the same as a nation. The U.K. and the British colonies constitute one state but many nations. Within the U.K. alone there are at least three nations. In a federal state, such as the U.S.A. or Australia, the same territory can form part of the federal state for certain purposes and a separate state for others.

The term state connotes both the government and the entire organization connecting that government with its individual subjects, and according to most theorists, the individual citizens as well. In its dealings with other states, however, a state acts only through its government and the agents of that government. In relation both to its own citizens and to other nations the state has some of the rights and duties of a legal person, e.g. it can own land and can sue and be sued in courts.

In the organization of any state it is possible to distinguish three separate functions: the legislative, the judicial, the executive. The first is concerned with law-making; the second with law interpretation and enforcement; the third with government and continuous supervision, and with external relations. These functions may be vested in separate bodies, as in the U.S.A., where congress exercises the legislative function; the supreme court, the judicial function; and the president, the

executive function. Or they may be more or less closely combined, subject to certain safeguards, as in the British constitution.

There is much disagreement concerning the functions of the state, particularly the extent of the executive function. It is agreed that the primary duty of the state is to secure the maintenance of order within the area it controls, and to defend its subjects and their property against attack from without or within. Its judiciary has the duty of securing obedience to the law, and of judging disputes and settling claims when submitted to it by individual citizens. But in regard to the executive, opinions range from the view that it should restrict its activities to the maintenance of the minimum framework of government to the view that it should organize the economic and social life of the community in detail. The former view is the individualistic; the latter, the collectivist or totalitarian.

Two other fundamentally different views of the state exist. The one regards the state as an end in itself, an entity greater than the subjects, a creation that it is their primary function to serve; the other view is that the state is only a means of maintaining and increasing the well-being of the people composing it. The one considers the aggrandisement of the state as the highest good; the other judges the greatness of the state according to the degree in which it ministers to its people. It is impossible to reconcile these two theories of the state. The two Great Wars were essentially a conflict between them. See Society; Sociology; Sovereignty.

State Department. The most important executive department in the government of the U.S.A., created 1789. Its head, entitled the secretary of state, ranks first among the members of the president's cabinet, and in the event of the death of both president and vice-president would succeed to the presidential office. He is sometimes called the American premier. The functions of the department correspond mainly to those of the British foreign office, but include also many other routine duties, e.g. the secretary of state is keeper of the great seal, which he attaches, together with his own signature, to all presidential proclamations and to the commissions of a large number of officers appointed by the president. He is moreover required to receive,

record, publish, and preserve all bills, orders, and resolutions passed by congress. The roll of secretaries of state includes many of the most famous names in American political history. The department is housed in the great State, War, and Navy building near the White House, Washington, D.C.

Staten Island. Island of New York, U.S.A. Coterminous with the co. and bor. of Richmond, New York city, it is situated at the mouth of the Hudson river, and is separated from Manhattan Island by the Narrows, the communicating channel of upper and lower New York bays. It covers an area of 70 sq. m. Villages, some built in colonial times, line the N. and W. shores. Behind are shipbuilding yards and industrial plants. The W. portion has many large market gardens. Pop. 174,441.

Staten Island (*I. de los Estados*). Island off the S.E. point of Tierra del Fuego, Argentina. It is rocky and mountainous and has a length of 45 m. Le Maire Strait separates it from King Charles's South Land. A lighthouse marks its E. extremity and an observatory is situated on New Year Island, 5 m. off the N. coast.

Stater (Gr., from *histanai*, to weigh). Name of standard gold and silver coins, current in the ancient Greek world. Of gold staters, the oldest were probably the double staters of Cyzicus and Phocaea, the value of which was low, owing to debasement of the coinage. The double stater of Lydia, first issued by Croesus, was purer. The Persian gold stater, called a daric after Darius, weighed two drachmae, and was current at Athens, where, as well as in Macedonia, staters which were of the same value were coined. Their value was about £1 2s. Silver staters or didrachms, worth a tenth of the gold staters, were coined in Asia Minor and Greece. See Drachma; Numismatics.

State Rights. Political doctrine in the U.S.A. It declares that each component state of the Union is a sovereign body in itself, and that the federal government has no power other than that expressly delegated to it by the individual states. The doctrine manifested itself in practical politics on several occasions in the decades immediately following the Declaration of Independence. The most serious case was that of South Carolina in 1832, which declared null a tariff measure of congress. That issue was compromised; but the whole matter

was subsequently brought to a head by the slavery question, which divided the South from the North, when the Southern states took up arms in the Civil War (1861-65), ostensibly to vindicate their right to secede from the Union, the logical outcome of the doctrine of state rights. The North, on the other hand, fought successfully to maintain the "Union one and indivisible," an object which involved the absolute negation of the state rights doctrine. The Civil War settled the matter for practical purposes. The doctrine is fully discussed in Bryce's *American Commonwealth*. See United States.

States-General. Body representing the three estates of the French kingdom, the clergy, the nobility, and the commons. It was first called by Philip IV in 1302 to secure for himself popular support in his struggle with Pope Boniface VIII. The states-general had no legislative functions and could make their influence felt only by petitioning against grievances. Theoretically their consent was necessary for the imposition of general taxation, but they rarely met. Their criticism of the national finance when called by Louis XIII in 1614 led to their dismissal by that monarch, and they did not meet again until they were called by Louis XVI in response to general demand in 1789. It was decided that the clergy and nobility should be represented by 300 and the commons by 600 members, but when the members met, difficulties of procedure arose. Eventually it was agreed that all the deputies should meet and deliberate in a single chamber, which took the title of National Assembly (*q.v.*).

The term states-general was also applied to the representatives of the seven provinces of the old republic of the Netherlands (*q.v.*). This body met at The Hague and exercised sovereign power. The name survives in the parliament of the present kingdom of the Netherlands. See Representation.

Statice. Flowering plant of the family Plumbaginaceae, mostly growing on sea cliffs and mountains. It is the generic name of Sea Lavender (*q.v.*), and was formerly that of Thrift (*q.v.*).

Static Electricity. Electricity at rest, as contrasted with current or dynamic electricity. The phenomena concerned with static electricity are due to the electrostatic forces of attraction or

repulsion arising directly from the charges. See Electricity.

Statics (Gr. *statikos*, relating to standing). Branch of mechanics which deals with bodies and forces or systems of bodies and forces in equilibrium. One of the fundamental propositions of statics is that the sum of the moments of all the forces about any axis must vanish. The potential energy of a statical system is a minimum. Statics also treats of the relations of strains and stresses of a body. Many problems of statics may be solved by graphical methods. See Equilibrium; Graphic Statics; Mechanics.

Stationers' and Newspaper Makers' Company. London city livery company. Arising from

Stationers' Company arms

the Ancient Brotherhood of Text Writers, or Scriveners, it was incorporated as the Stationers' Company in 1557 to foster the publishing and stationery trades. Mary I and Philip granting its first charter. Still maintaining practical connexion with the trades named, it once had the monopoly of printing in England, and until 1912 works could be "entered" or registered for copyright purposes at Stationers' Hall under the Copyright Act, 1842. Until 1771 the company had the sole right to print almanacs. The site of the hall in Stationers' Hall Court, Ludgate Hill, was purchased in 1611; the present hall was built 1670-74 after the Great Fire, refaced with stone in 1800, and extended in 1887. It contains a stained-glass window in memory of Caxton. The company, in conjunction with Middlesex county council and Hornsey borough council, maintains a day grammar school for about 500 boys at Hornsey. There are a corporate income of £1,600 and a trust income of £3,100.

Stationery Office, HIS MAJESTY'S. Government printing and publishing organization. Established in 1786, it issues White papers, Blue books, books on a wide range of subjects, pamphlets of the various ministries, and periodicals to the public at home and abroad, and has a head office at 421, Oxford Street, London, W.1, and sales offices in London, Edinburgh, Cardiff, Manchester, and Bristol. Copyright in all British government documents is vested in the controller. The annual out-

put includes telephone directories, rationing documents, national savings certificates, pension and allowance books, and national insurance stamps. The London Gazette has been issued twice weekly since 1665, and the daily and weekly Hansard (*q.v.*) is also a publication of H.M.S.O.

Stations of the Cross. Popular name of a devotional practice in the R.C. Church. A series of pictorial representations of scenes in the Passion is usually placed on the walls of R.C. places of worship, and during Lent and in Passion Week the faithful proceed from one to another, kneeling and reciting appropriate prayers before each. The stations usually number 14. The devotion dates from 1726, when the indulgences to be gained by a visit to the holy places of Jerusalem were declared obtainable by visits to representations of the Stations of the Cross.

Statistical Society, ROYAL. Society founded in 1834, and incorporated by royal charter in 1887. Its object is the study of statistics of various kinds. During the session papers are read, and afterwards published in the society's journal. The offices are at 4, Portugal Street, London, W.C.2.

Statistics. Term for statements of facts expressed numerically and placed in relation to one another. Statistical analysis is the process of classifying these statements and clarifying those relationships which are relevant to the inquiry in hand. Although popularly associated chiefly with economics and other social sciences, statistical analysis can be utilised in any field of inquiry in which adequate numerical data can be collected.

Trained statisticians play an important part in business, in government, and in scientific research of all types. The usefulness of statistics has come to be gradually appreciated in business as the scale of operation has expanded so that it is beyond the capacity of any individual to grasp all the details of production and sales. For example, the village shopkeeper knows his customers and their individual requirements and thus needs only the simplest records in order to carry on his business. The manager of the multiple store, however, cannot himself know all the facts and requires numerical records which can be summarised and analysed in order to provide him with the data on which to base his decisions; in short, he requires statistics. Parallel developments in public

administration have led to a parallel dependence. In medieval times only the most primitive statistics were required for estimating the govt's revenue and expenditure in the limited field of activity with which govt. was concerned. The growth of trade and industry and the development of a scientific outlook on social and economic problems led to extensions in the fields in which statistics were collected and to refinements in the methods of analysis. Thus by the end of the 19th century most important countries had regular pop. censuses and steadily improving vital statistics, officially collected, as well as the customary records of finance and trade and statistics collected for special purposes.

Government Use of Statistics

The growth of govt. intervention in social and economic matters during the 20th century greatly enhanced the importance of statistics, for in the interests of good administration it became necessary to extend the field in which quantitative data are collected and to develop methods for estimating and measuring social phenomena with which the govt. is concerned. The problems arising from the Second Great War, together with the desire to plan economic activity to prevent violent fluctuations in employment, led to attempts to draw up budgets of all national economic resources (in addition to the traditional financial budgets of govt. revenue and expenditure) as well as in some cases budgets of international resources, *e.g.* in connexion with the European Recovery Programme. Much statistical analysis has been applied to such widely different subjects as research into the nature of matter and the application of scientific discoveries to agriculture.

The difficulties of collecting reliable data, of making estimates where data are seriously incomplete, and of selecting the most appropriate methods of analysis differ from inquiry to inquiry. Statisticians therefore require considerable background knowledge of any subject of inquiry before they can apply their techniques. Nevertheless, many of the problems and, also, of the fundamental methods of analysis are common to all. Certain preliminary processes are essential: definition of the universe to which the inquiry relates, definition of the limitations of the data available about that universe, choice of appropriate systems of classifica-

tion of the data, and classification and tabulation. However elaborate the later stages of analysis may be, failure properly to complete these elementary steps detracts from the reliability of the results and may lead to serious errors. To take a single example, in comparing the age composition of the pop. of Great Britain at two dates, care must be taken to compare the same universe at both times, *e.g.* aliens resident in Great Britain must be included at both dates or excluded at both dates; and identical, or comparable, systems of classification of ages must be used for both dates.

One of the most important functions of statistics is to find appropriate measures for describing data. For this purpose averages of various sorts and measurements of variation, or dispersion, about the averages are commonly used. These measures may be simple or complex according to the type of data and the information required. Once they have been calculated the statistician possesses a way of comparing the relevant characteristics of the data, *e.g.* the yield per acre of wheat on farms of different types.

Statistical Significance

Application of the theory of probability enables the statistician to decide whether the differences within a group, or between several groups, are statistically significant, in the sense of whether they are too large to be attributed to chance influences on the data. This technique is particularly important when the data collected relate only to a sample, or samples, of the whole universe to which the inquiry refers. In these cases the statistician can decide, by calculating the significance of variations within a sample, or between samples, whether the samples can be regarded as representative of the universe from which they are drawn. The analysis of samples is of fundamental importance in current statistical inquiries in the social sciences, business, and the natural sciences, as by it information can be obtained where it is impracticable to investigate the whole universe. The ministry of Labour's inquiry of 1937-38 into working-class expenditure provides a good example of the use of sampling technique.

Correlation analysis is used to measure possible relationships between phenomena, *e.g.* rainfall and wheat yields. A high positive correlation coefficient between high yields and high spring rain-

falls in different places, and low yields with low spring rainfall, would indicate that high yields tend to occur in places of high spring rainfall and vice versa. The greatest care has to be used in interpreting correlations, for they measure degrees of co-existence of occurrences rather than demonstrate causal relationships.

Statistical methods have also been evolved to analyse time series, i.e. records of data over periods of time, such as rainfall in some place over periods of days, years, etc. The main trends can be isolated from seasonal or random changes and may be used in some cases as a basis for forecasting. Analysis of time series is of particular importance for investigations of fluctuations of economic activity, and it is in this connexion that the technique of index numbers has been developed to provide summary measurements of economic changes.

Bowley, 1937; Statistical Methods of Research Workers, R. A. Fisher, new ed., 1938; Elementary Manual of Statistics, A. L. Bowley, 6th ed., 1939; Statistics (Home University Library), L. H. C. Tippett, 1943; Advanced Theory of Statistics, M. G. Kendall, 2 vols., 1946.

Statius, PUBLIUS PAPINIUS (c. A.D. 45-96). Roman poet. Born at Neapolis, the son of a well-known grammarian, he accompanied his father to Rome, where he became famous for his successes in the poetic competitions which were a fashionable event in that age. Apart from his gift of improvisation, Statius was a facile and accomplished versifier, ranking high among Latin poets of the Silver Age, and his works enjoyed a great vogue in the Middle Ages. The most notable of Statius's works is the *Thebaid*, an epic poem dealing with the war of the Seven against Thebes. Less known is a collection of miscellaneous poems, *Silvae*. Statius left Rome in chagrin at not receiving the prize in the Capitoline competition in 94, and returned to Neapolis, where he died.

Stator. Stationary part of an asynchronous (alternating current) induction motor. A stator carries the coils through which the primary current passes. *See* Current.

Statuary. In art, a sculptor who makes statues in the round. The term is generally used nowadays in connexion with the more

commercial types of sculpture, e.g. garden statuary. Statuary may also mean a collection of statues. *See* Sculpture.

Status (Lat., position). Term used in ancient legal systems to indicate the standing that a man had in law. Thus in Roman law the status of a free man and a slave, of a father and a son, of a citizen and an alien, were quite different. It is still used in a general sense.

Status Lymphaticus. Condition characterised by increase of the lymphatic tissues of the body and of the lymphatic glands. The thymus gland, an organ present in childhood which normally gradually atrophies as adult life is reached, is found to persist in the subjects of status lymphaticus. The spleen is also enlarged, and the heart very often, if not always, exhibits fatty degeneration. Persons suffering from this condition are often fat and flabby, but may not exhibit signs of ill-health. Such persons are bad subjects for the administration of an anaesthetic.

Statute (Lat. *status*, position). Literally, something fixed. It is used for a law enacted by a parliament or other legislative body. Many of the early laws of England are known as statutes, e.g. statute of labourers, statute of uses, etc. The practice was revived in 1931, when in order to mark the outstanding importance of the Act of parliament of that year which established "dominion status," the Act was called the Statute of Westminster. *See* Act of Parliament; Bill; Law.

Statute Law. Law made by the supreme legislative authority, e.g. an Act of parliament. There is no difference in force or effect between a statute and any other kind of law. According to the English rule, a penal statute must always be interpreted strictly, or narrowly; while a remedial statute must be interpreted broadly and generously. This rule only applies where the strict literal and grammatical meaning of the words is susceptible of two interpretations.

In Great Britain it is customary to pass, every now and then, a Statute Law Revision Act, the object of which is to repeal obsolete sections or words of old statutes, or such as conflict with more modern Acts of parliament.

Properly speaking, the Acts of any session of parliament constitute only one statute; and that is why every Act is numbered. Thus 9 and 10 Geo. VI, chap. 22, means the twenty-second chapter of the statute passed in the session

of parliament which began in the ninth year of the reign of George VI and finished in the tenth year. *See* Law.

Statutory Declaration. Statement made under the Statutory Declarations Act, 1835. Before that date it was necessary for many purposes of trade to make a large number of statements on oath. It was thought that this led to the oath being lightly regarded, and the Act enabled a declaration to be substituted for the oath, except in the oath of allegiance and in judicial proceedings. A person making a false statutory declaration is liable to fine and imprisonment for not more than two years.

Statutory Instrument. Document to which the Statutory Instruments Act, 1946, applies. The Act was passed as a result of a report of the select committee on statutory rules and orders, which recommended alterations in the procedure under which delegated legislation by order in council or a government department was controlled by parliament. The Act applies to all orders issued by any body to which power to legislate is delegated by parliament.

Staubach. Waterfall in Switzerland, in the canton of Berne. It is close to Lauterbrunnen, 8 m. S. of Interlaken. It drops 980 ft. from a jutting rock and is blown into a silvery veil of spray, whence its name "dust stream."

Stauning, THORVALD (1873-1942). A Danish statesman. He was born in Copenhagen, Oct. 26, 1873, and began work as a cigar sorter. In 1906 he entered parliament as a trade unionist and a Social Democrat, and from 1910 to 1924 led the Socialist party. Stauning then became prime minister for two years; he was again prime minister in 1929 and retained that office until his death, representing Copenhagen as M.P. He codified national insurance in 1933. In the First Great War he was thought to have had pro-German sympathies; in the Second he protested vigorously against the occupation of Iceland by Allied troops. On April 9, 1940, when the Germans delivered their ultimatum to the Danish government, Stauning advised its acceptance. He died in Copenhagen, May 3, 1942.

Staunton. City of Virginia, U.S.A., the co. seat of Augusta co. It is 133 m. W. by N. of Richmond, and is served by rlys. Bricks, flour, and agricultural implements

Stavanger, Norway. Air view of the city, showing some of the many islands in Stavanger Fjord

are manufactured. Founded in 1745, Staunton was incorporated in 1761, and chartered as a city in 1870. Woodrow Wilson was born in Staunton, and here in 1908 the commission form of government was first tried, the voters electing a council which appoints a city manager. Pop. 13,337.

Staunton, HOWARD (1810-74). British chess player and Shakespearian scholar. He defeated Fournie de Saint-Amant in a great chess match in Paris in 1843, and was for many years one of the best exponents of the game, beating such celebrated players as Popert, Horwitz, and Harwitz. Staunton was ultimately defeated by Anderssen at the London tournament in 1851. He wrote many standard works on chess, also edited *The Chess Player's Chronicle* and *The Chess World*. He published an edition of Shakespeare, illustrated by Sir John Gilbert, 1857-60, edited a facsimile of the first folio, 1866, and published a number of emendations of the text. Staunton died June 22, 1874.

Staurolite (Gr. *stauros*, cross; *lithos*, stone). A hydrated aluminum-iron silicate. A little magnesium and manganese are often present. So called from the cruciform twinned crystals which are a common form of the mineral, it has a brown vitreous lustre. It is widely distributed in metamorphic rocks, like gneiss, and is often associated with garnet, tourmaline, and syenite. In Tirol and Brittany twinned crystals were looked upon by the superstitious as having fallen from the skies, and were worn or carried as charms to ward off the evil eye.

Stavanger. City and seaport of Norway. It is 105 m. S. of Bergen,

190 m. S.W. of Oslo, on the Stavanger Fjord, an arm of the Bukke Fjord. The cathedral was founded in the 11th century by Bishop Reinald, an Englishman; the later Gothic edifice, considered one of the finest in Norway and built in place of the earlier church, burnt down in 1272, was restored in 1866. Textiles of wool, flax, and cotton, soap, preserves, margarine, and earthenware are the main products; there are iron foundries and shipyards. Fishing and fish-curing are the chief occupations. Founded in the 8th century, the town has been frequently burnt down and rebuilt. Stavanger was occupied by German troops on April 9, 1940, the first day of their invasion of Norway. The airport provided a base from which to assail British shipping off the Norwegian coast, and was frequently attacked by the R.A.F. The city was liberated when the German forces in Norway capitulated, May 8, 1945. Pop. 49,218.

Stave or **STAFF**. In music, the lines upon which, with the intervening spaces, notes are placed in order to indicate pitch. The most convenient number is found to be five, and a clef (*q.v.*) is placed upon it to fix their alphabetical names and their pitch. All staves are really selections from the great staff of eleven lines, which covers the range of the human voice from bass to soprano.

In staves the position of the clefs is immutable; it is only the accompanying lines which change. The staves used for piano music are practically the great staff, with the middle line removed for greater clearness in reading. In medieval times staves with six or

seven lines were often used, and in plainsong four lines are the practice.

The germ of the staff dates from the use of a single line in red about A.D. 900, to show tenor F in the neume notation. Later, a second line in yellow was added for C a fifth higher. To Guido d'Arezzo belongs the credit of having developed this germ into a staff in which both lines and spaces were utilised. Hucbald, it is true, used parallel lines, but he made use only of the intervening spaces. See *Staff*.

Staveley. Village of Derbyshire, England. It is 4 m. by rly. N.W. of Chesterfield. Standing on a coalfield, its chief industries are coal mining and iron working, especially the manufacture of cast-iron pipes. Hollingwood, a model village adjoining Staveley, was built to house employees of the great Staveley Coal and Iron co., which in 1948 published *Staveley Story*. The church of S. John the Baptist, an early English building restored, contains monuments to the Frecheville family. Pop. est. 16,000.

Stavisky Riots. French financial and political disturbances in 1934. These followed a fraud perpetrated by Serge Stavisky (1866-1934), a naturalised Frenchman from Russia, who had been fraudulently floating bonds through the state-controlled *Crédit Municipal* of Bayonne. President Lebrun ordered a search for Stavisky, for whom a warrant had been issued on a charge of disposing of worthless bonds valued at about £8,000,000 to state pawnbroking establishments, insurance companies, and banks. This was only part of a vaster scheme to raise money for a huge land speculation in Central Europe. Stavisky shot himself at Chamonix and died Jan. 9, 1934. The scandal had serious repercussions, leading to the fall of two governments and to violent outbreaks of rioting in Paris, Feb. 6-12, when Royalists and Communists fought each other in the streets, thousands of people being injured, and a general strike was declared.

Stavropol. Former name of Voroshilovsk (*q.v.*), a town of the R.S.F.S.R.

Stawell. Township and rly. junction of Victoria, Australia. It stands on the main Melbourne to Adelaide line, 150 m. S.E. of the latter city. The district is agricultural and contains a few gold mines and a number of freestone quarries. Pop. 4,840.

Stays. Nautical term for the supports which form part of the standing rigging of a ship. They take their name from the spars they support, as, for example, the topmast-stay, which holds the topmast in position. "Staying forward" a mast is making it lean forward. A vessel is in stays when she is going from one tack to another. Missing stays is when a vessel fails to respond to the helm and go about. *See Ship.*

Stead, WILLIAM THOMAS (1849-1912). British journalist. Son of a Congregational minister, he was

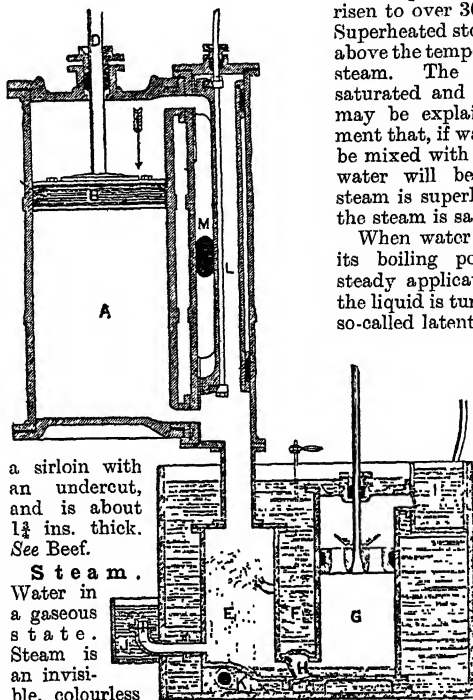

William T. Stead

born at Embleton, Durham, July 5, 1849, and educated at Silcoates school, Wakefield. Leaving a merchant's office to edit *The Northern Echo*, Darlington, 1871-80, he was assistant editor of *The Pall Mall Gazette*, 1880-83, and editor, 1883-89. He founded *The Review of Reviews*, 1890, started a penny Masterpiece Library, a series of Penny Poets, and the highly popular penny Books for the Bairns, and wrote political and other works. He was drowned when the *Titanic* foundered in the Atlantic, April 15, 1912.

Stead was one of the prominent publicists of his time, a founder of the "new journalism"; he popularised the interview, travelled on the Continent and in the U.S.A. as peace propagandist, advocated a strong British navy, was much concerned in social work, especially in criminal law amendment, and was influenced by spiritualism. His most startling contribution to journalism was his series of articles in *The Pall Mall Gazette*, 1885, under the title *The Maiden Tribute of Modern Babylon*. This exposure of the white slave traffic was based on personal research (for which, being technically guilty of abduction, he suffered three months' imprisonment) and had as direct result the passage of the Criminal Law Amendment Act, 1885. A memorial, on the Thames Embankment, erected by British and American journalists, was unveiled July 5, 1920. *Consult My Father*, E. W. Stead, 1913; *Life*, F. Whyte, 1925.

Steak. Thick slice of meat or fish. Beefsteak, which is boneless, is cut from the best parts of the

animal, and includes rump steak, buttock steak, and fillet steak (from the undercut of a sirloin). A Porterhouse steak is taken from

Steam Engine. Early type of double-acting condensing engine. A, steam cylinder. B, steam piston. D, piston rod. E, condenser. F, injection cock. G, air pump. H, foot valve between condenser and air pump. I, hot well. J, blow valve. K, cold water pipe. L, connecting eduction pipe. M, steam pipe.

a sirloin with an undercut, and is about $1\frac{1}{4}$ ins. thick. *See Beef.*

Steam.

Water in a gaseous state. Steam is an invisible, colourless gas with a specific gravity of .625 compared with that of air at the same pressure. The temperature at which water is converted into steam varies with the pressure. At a pressure of 14.7 lb. per sq. in., or 760 mm. of mercury, and at mean sea level, water is converted into steam at a temperature of 100°C . (212°F). The temperature of boiling water falls or increases as the pressure, the relation between the two having been worked out by Regnault. The white cloud which is seen issuing from a vessel containing boiling water is steam which has condensed into small particles of water on contact with air.

One pound of steam at normal atmospheric pressure occupies a minimum volume of 26.36 cu. ft., or steam occupies 1,660 times the volume it does as water. Steam at

the temperature at which it is formed from water is called saturated steam. The pressure of saturated steam at 100°C . is 14.7 lb. to the sq. in., but at 215°C . it has risen to over 300 lb. to the sq. in. Superheated steam is steam heated above the temperature of saturated steam. The difference between saturated and superheated steam may be explained by the statement that, if water at boiling point be mixed with steam, some of the water will be vaporised if the steam is superheated, and none if the steam is saturated.

When water has been raised to its boiling point it requires a steady application of heat before the liquid is turned into steam, the so-called latent heat of steam.

For the use of engineers special steam tables are published, which give the absolute pressure in pounds per sq. in., the temperature of the steam corresponding to that pressure, the temperature of the water at the pressure, and various other figures. From these tables, by looking at the pressure gauge, say of a boiler, the temperature can be at once obtained.

In addition to its commonest use in engines, steam is used for heating purposes, for disinfection, cleansing operations, as a fire extinguisher, and other uses. *Consult Steam Power*, W. E. Dolby, 1920; *Steam, Air, and Gas Power*, W. H. Severns and H. P. Degler, 1940.

Steam Engine. Machine for the conversion of heat energy into useful work by means of the expansive force of steam. Many early attempts were made to use steam

Barker's mill (*q.v.*), steam replacing the jets of water in the latter. Giovanni della Porta at the beginning of the 17th century adapted another of Hero's inventions, his well-known fountain, replacing the

expanding air used in the latter with steam, and in 1655 the marquess of Worcester is credited with the invention of a steam engine for the pumping of water. An important application of steam

as a motive power was made by Thomas Savery, who patented an engine in 1698. Essentially it consisted of a cylinder into which steam entered and forced out a charge of water, sucked into it by a previous charge of steam that was suddenly condensed by a jet of cold water allowed to flow over the outer surface of the cylinder. Savery's engines were erected in many parts of England for pumping water, and the modern pulsometer pump is constructed on the same general principle. To Savery is due also the first use of the term horse-power.

Savery's engine was considerably improved by Thomas Newcomen and John Cawley, who introduced a piston, driven down by atmospheric pressure as a vacuum was created in the cylinder by the condensation of the steam. Newcomen adopted the idea of the piston from a French engineer, Denis Papin. Newcomen's engine, like Savery's, was used for pumping water. The steam in the cylinder was condensed by a jet of water inside, instead of a flow of cold water outside, as in Savery's.

Both engines were extremely wasteful in consumption of steam.

Steam Engine. Triple-expansion marine engine, built for the S.S. Lady Kildare. Its indicated horse-power is 1,600
By courtesy of William Beardmore & Co., Ltd

The next important step forward came from James Watt, who patented a separate condenser in 1769. The double-acting engine followed. From the time of Watt's improvements the advance of the steam engine was rapid. Richard Trevithick applied it to the first locomotive to run on rails in 1804. Hornblower a few years previously brought out the first compound engine, and the improvements which followed were mainly those based on a wider choice of materials, and extended research on strength of materials, properties of steam, heat transmission, etc.

Steam engines may be classified as single-acting or double-acting, condensing or non-condensing, or of the high-speed or low-speed types. When the expansion of the steam is carried out in two or more consecutive cylinders we have as a further classification the single, compound, triple, or quadruple expansion engines.

Essentially a steam engine consists of a piston and cylinder with the necessary gear for converting reciprocating motion of the piston into rotary motion of a shaft. Admission to and exhaust from the cylinder are regulated either by slide valve actuated by an eccentric or by poppet valves actuated by trip gears. Large engines are fitted with condensers, which reduce back pressure. The diag. (p. 7768) shows essential parts.

C is the closed cylinder containing valves V^1 , V^2 , V^3 for the admission and exhaust of steam to the cylinder. P is the piston, a steam-tight fit in the cylinder, and is connected by a piston rod R to a crosshead G, sliding between guides. The crosshead is connected by the connecting rod R^1 to the crank K. A flywheel is usually fitted to control speed fluctuations during a revolution.

Horizontal engines are those in which the axes of the cylinder and piston are horizontal, and offer the general advantages that the working parts are of easy access and the weight of the engine can be distributed over a larger area. In the vertical engine the axes of the cylinder and piston are vertical.

When the motion is transmitted directly to the crank from the piston by a connecting rod, the engine is called direct acting. In the oscillating engine (now obsolete) the piston rod itself connects with the crank direct, and the cylinder oscillates with the motion, being mounted on trunnions for the purpose. The terms high-speed and low-speed usually refer to

speeds of revolution, but piston speeds (ft. per min.), on which the h.p. depends, may be the same. See Condenser; Crosshead; Flywheel; Governor; Locomotive; Railways; Valve; Watt, J. Consult Heat Engines, D. A. Low, 1920; Ripper's Heat Engines, 1948.

Steam Gauge. Particular form of manometer used for showing the pressure at any moment in a steam boiler or other steam container. The instrument may also be used to show the pressure of compressed air or gas or of water under pressure. See Pressure Gauge.

Steam Hammer. Power-driven hammer. The invention of James Nasmyth about 1842, the

Steam Hammer. Diagram showing main working parts of a Massey power hammer. See text

tup, or massive striker, of the steam hammer was attached to the lower end of the piston rod of an inverted cylinder. Steam was admitted below the piston to raise the hammer, and above it to accelerate the fall, by the movements of a lever controlling a steam-valve. Nasmyth's partner, Robert Wilson, introduced some valuable improvements which made the hammer self-acting. The figure gives details of a Massey steam hammer with overhanging frame, and a tup H moving in guides. The steam-valve is automatically moved up and down by means of the curved lever J—against which a roller on the tup strikes as the tup falls and rises—and steam is admitted alternately above and below the piston. The range of movement of the valve, and consequently of the tup, varies according to the position of lever M, which can be set in any one of several notches. For hand-working, the valve is moved directly by hand lever Q.

The stop-valve A, controlled by lever B, regulates the amount of steam admitted and therefore the force and speed of the blows. Some steam hammers are hand-controlled. The steam pressure used is 60–80 lb. per sq. inch.

The average force of the blow delivered depends on the weight of the tup, the speed at impact, and rigidity of support. Hammers for very heavy work have tups of over 100 tons, but very large hammers have been almost completely superseded by hydraulic presses. See Pile-driving.

Steam Roller. This machine is described under Roller.

Steam Ship. Details of steamships are given under Ship.

Steam Turbine (Lat. *turbo*, whipping top, reel). Machine for converting the pressure energy of steam into kinetic energy and utilizing this kinetic energy to produce rotary motion of a wheel or drum which transmits power. There are two principal types: (1) reaction turbines, operating through the reaction of jets of steam issuing from nozzles, which move in opposite direction to the jets—the earliest

example is Hero's engine (130 B.C.); (2) impulse turbines, in which jets of steam from stationary nozzles impinge upon suitably shaped blades on a wheel, causing it to rotate—the earliest example is Branca's engine (1629).

A simple type of impulse turbine was introduced by De Laval, of Stockholm, in 1888. It consists of a set of suitably shaped nozzles in which the steam expands from boiler pressure to condenser pressure, thus converting heat energy into kinetic energy (Fig. 1). The issuing steam is directed into

Steam Turbine. Fig. 1. Diagram showing arrangement of nozzle and buckets of a De Laval impulse turbine

curved blades on the rim of a rotating disk, the impulsive force on the blades driving the wheel, which delivers power through a reduction gear to a dynamo or other machine (e.g. a centrifugal separator). For economical working the speed of the wheel rim should be about half the speed of the issuing steam. With a boiler pressure of 135 lb.

Steam Turbine. View of gears and casing of a 1,200-h.p. engine. Top, right, De Laval steam turbine wheel with nozzles, illustrated diagrammatically in Fig. 1

creasing the diameter of the drum on which they are mounted. Theoretically each element should be a little larger than the one before, and in the larger turbines the casing is tapered to permit of this, but for constructive reasons the increase is frequently carried out in

per sq. in. abs. and condenser pressure 2 lb. per sq. in. abs. (26-in. vacuum) the velocity of issue is about 4,500 ft. per sec. and the wheel rim speed should be about 2,000 ft. per sec. This would involve excessive centrifugal stresses both in disk and blading, and the speed in practice seldom exceeds 1,000–1,200 ft. per sec. The consequent reduction in economy limits the practical sizes of units to comparatively small values. Owing to the high revolution speed (30,000 a min. in some cases) a flexible shaft supports the disk and compensates for any slight degree of unbalance.

The first practical steam turbine, running at a moderate speed and utilising the full expansion in a large number of stages with small pressure drops in each stage, was the Parsons compound reaction turbine, introduced in 1884. Each "stage" consists of a row of fixed guide blades and one of moving blades, the latter being attached to a rotating drum and projecting outwards from it till they nearly touch the casing, while the former project inwards from the casing till they nearly touch the drum. In order to accommodate the increasing volume of the constantly expanding steam, these elements are made gradually larger from the high-pressure end of the turbine to the low-pressure or condenser end, by lengthening the blades or in-

steps, each of which contains several rows of blades of the same size (Figs. 2 and 3). At each stage the steam undergoes a small drop of pressure with gain of velocity, leaving the moving blades with a push-off or reaction effect. A large number of stages is necessary to ensure that the steam is fully expanded.

Fig. 3 shows the essential features of the earlier type. Steam enters at A and expands through alternate rows of standing and running blades, finally exhausting at the low-pressure end. Since the blades are non-symmetrical (Fig. 2) there will be an end thrust on the rotating drum; this is compensated by balance pistons B, C, and D as

shown, any unbalanced thrust being taken by a thrust block which also serves for axial clearances of blading. Since there is a drop of pressure in the running blades on the drum as well as in the standing blades on the casing, leakage of steam past the tips of the running blades is possible and this is more pronounced in the smaller sizes of turbine. In later types adjustable axial clearance, or "end-tightening," is used at the high-pressure end, where the diam. is small and the pressure drop per stage is comparatively large.

Introduction of Generators

When Sir Charles Parsons first turned his attention to the steam turbine it was with the object of applying it to the driving of electric generating machinery, and so suitable did it prove for this purpose that turbo-generators came to be universally used in steam power stations, where units of up to 150,000 h.p., using superheated steam at pressures of from 600 to 1,200 lb. per sq. in., with stage feed heating by "bleeding" at a number of points of the expansion, are in operation. Research and experiment on blading shapes and materials, increasing the number of stages of expansion and use of

Steam Turbine. Fig. 2. Diagram illustrating principle of reaction turbine blading

"double-flow" exhaust, have reduced specific steam consumption to a figure much below that of the best reciprocating engines.

The use of turbines for the propulsion of ships dates from 1897, when the Turbinia, a little vessel with the then almost incredible speed of over 32 knots, made her appearance at the naval

Steam Turbine. Fig. 3. Diagram showing essential features of the earlier type of reaction turbine blading. See text

review held in that year. Since that date turbines have been fitted in fast cross-Channel steamers and in the fastest Atlantic liners. The first warship to be driven by steam turbines was the *Dreadnought* (*q.v.*); large warships came generally to be driven by turbines. For best efficiency the turbine should revolve quickly and the propeller slowly; to reconcile these requirements first single reduction and later double reduction gearing was interposed between turbine and propeller shaft. This makes it possible to split up the turbine into two or three elements driving the same gear wheel, thus saving space and allowing different speeds to be arranged for the different elements. In marine practice a high-speed turbine often drives a dynamo which supplies current to motors on the propeller shafts. Speed control and reversing can be effected from the bridge.

In order to obviate end thrust and reduce leakage losses, Rateau introduced a pressure-compounded impulse turbine (Fig. 4). Turbines constructed on this principle consist of a number of separate com-

Steam Turbine. Fig. 4. Diagram illustrating the Rateau pressure-compounded impulse turbine

partments, in each of which is a bladed wheel. The steam flows through all the compartments in series, passing from one to the next through nozzles in which a velocity corresponding to the pressure drop is generated. By adopting a sufficient number of stages, the velocity of the steam entering each can be reduced to any desired value, and thus can be made appropriate to the desired blade speed of the wheel on which it acts. The number of stages adopted will depend upon the total pressure drop, the successive pressure drops being so adjusted that an equal steam velocity is generated and utilised in each. In order to reduce the num-

ber of stages, and consequently to cheapen the machine, Curtis adopted the principle of "velocity compounding." In the early Curtis turbine the wheel of each stage, instead of carrying only a single row of buckets, was fitted with two, three, or even four rows. Between these, fixed guide blades projected from the casing, the function of these blades being to turn back the steam issuing from one row of running buckets and direct it upon the next. By this method it was hoped to use efficiently in each stage a much higher steam velocity than could be dealt with by a single row of blades. Many large machines were constructed on these lines, having only from three to six pressure stages, but the type was less efficient than a number of single-stage wheels. Single Curtis wheels are, however, sometimes used for the first stage of turbines in order to save space and first cost; also to increase the rigidity of the shaft.

In the earlier years the Parsons turbine was definitely more economical in heat consumption than the Rateau, but later developments produced machines between which there was little to choose on the ground of economy. Many turbines with impulse stages at the high-pressure end and reaction stages at the low-pressure end are in use. The Ljungstrom turbine is a reaction machine with radial flow and has no fixed rows of blades; in it the blades which correspond to the fixed blades of other turbines themselves rotate in the opposite direction to that of the other blades, each set of blades projecting from the face of a disk, and the rows interleaving with those of an opposing disk. In this turbine both shafts rotate in opposite directions and each carries its own electric generator. Most difficulties in construction have been overcome and some large units are in successful operation.

Since full expansion of the steam down to the back pressure is impracticable in a reciprocating steam engine, the power can be augmented by arranging for the exhaust steam to drive a turbine. This is convenient particularly for ship propulsion, since reversing does not then require a separate turbine. The turbine can drive an additional propeller by gearing or can generate electricity which can either drive a motor or reheat the steam as it passes from one cylinder to the next.

A later development in some large high-efficiency power stations

was the addition of a "topping" turbine to the existing plant. For instance, boilers working at 250 lb. per sq. in. were replaced by boilers designed for 1,250 lb. per sq. in. New turbines took steam at 1,250 lb. and exhausted at 250 lb. This exhaust steam, after reheating, was supplied to the existing turbines, the result being an increase of output of more than 20 p.c. with 25 p.c. reduction in fuel consumption per kWh. See *Gas Turbine*; *Turbine*.

Stearic Acid (*Gr. stear, fat*). Fatty acid, $C_{17}H_{35}COOH$. First described about 1820 by Chevreul, it occurs widely diffused throughout the animal kingdom, combined with glycerine, and constitutes the bulk of hard fats, such as suet and tallow. It is also found in many vegetable fats, such as palm oil and shea butter. Stearic acid is made on a commercial scale by decomposing low-grade tallow with sulphuric acid or superheated steam under pressure; the fats are split up in the process, the glycerine mixing with the water and the stearic acid floating on the surface. From this product pure stearic acid can be made by crystallisation from alcohol. Stearic acid, a white, lustrous, crystalline substance, forms stearates with the alkalis and alkaline earths. The stearates are the chief constituent of all ordinary soaps. Stearic acid is used for making candles and polishes, in rubber compounds, as a substitute for wax in ointments, and when partly neutralised as the basis of vanishing creams.

Stearin. The glyceride of stearic acid which occurs in a greater or less degree of purity in many natural fats. Stearin can be decomposed into glycerine and stearic acid by heat, and can be synthesised by heating together glycerine and stearic acid. The term stearin is applied to commercial stearic acid, and also to fats from which the liquid portion has been removed by pressure. The last-mentioned stearins, employed in the manufacture of margarine, are distinguished as lard stearin, cotton stearin, or palm stearin according to the fat employed in their preparation.

Steatite. Variety of talc, also known as soapstone (*q.v.*).

Stedman, EDMUND CLARENCE (1833-1908). American poet and critic. Born at Hartford, Conn.,

Edmund Stedman,
American poet

Oct. 8, 1833, he was educated at Yale. By 1859 he was on the staff of The New York Tribune, and during 1861-63 he was correspondent in the Civil War for The New York

World. His Poems, Lyrical and Idyllic, appeared in 1860, his collected poems in 1897, and he achieved a great reputation by his volumes of criticism, which include Victorian Poets, 1875; Poets of America, 1885; Nature and Elements of Poetry, 1892. He died Jan. 18, 1908.

Steed, HENRY WICKHAM (b. 1871). British journalist. Born Oct. 10, 1871, son of a Suffolk solicitor, he was educated at Sudbury grammar school and

H. Wickham Steed,
British journalist
Russell

he was in 1918 associated with Northcliffe in directing propaganda in enemy countries. Wickham Steed was editor of The Times, 1919-22; then for eight years he owned and edited The Review of Reviews. A lecturer on European history at King's College, London, 1925-38, he frequently broadcast on world affairs for the B.B.C. overseas service. An authority on Germany and Central Europe, he published many books on Hitler; also The Hapsburg Monarchy, 4th ed. 1918; Through Thirty Years, 1924; A Way to Social Peace, 1934; The Doom of the Hapsburgs, 1937; Words on the Air (broadcast talks), 1946.

Jena, Berlin, and Paris universities, and became The Times correspondent in Rome, 1897-1902, and Vienna, 1902-13. As that newspaper's foreign editor,

for the steelmaking furnace. There are three chief steelmaking processes in use, the Bessemer, the open hearth, and the electric arc; each of these has modifications, but all utilise the same fundamental principle of refinement, *viz.* oxidation of the impurities. In the Bessemer process, the previously melted charge is oxidised by the blowing of air. In the open hearth and the electric arc processes, oxidation is effected by the oxidising nature of the furnace atmosphere, and by the addition of iron ore. Following the oxidation of the impurities, excess oxygen is removed from the metal in all processes by the addition of de-oxidising agents, and the liquid steel is then cast into moulds to solidify. These moulds may be either of simple shape to provide ingots for forging or rolling, or designed to give castings of the desired form without the need for mechanical shaping, except possibly by machining.

Method of Casting

Although steel and other metals may be cast to shape, the optimum properties of the metals are not developed by this method of shaping. By casting into simple ingot form, and then using mechanical treatment to bring the metal to the desired size and shape, the properties of the metal are improved. This improvement is due mainly to the greater uniformity of the metal structure after mechanical treatment, or "working."

The solidified ingots are removed from the moulds, reheated slowly to a temp. which depends on the composition of the steel (usually about 1,100° C.), and then forged or rolled. This operation is classed as hot working, because the working of the steel is done at a sufficiently high temp. to prevent the steel from hardening during the deformation. Rolling is the cheapest way of hot working, but it is not so effective in breaking down the irregularities of the cast structure as is forging. Hammer forging quickly breaks down the cast structure on small ingots, and is extensively used for working tool steels, but press forging is more efficient for large ingots.

The final sizing and shaping may be done by hot working or by cold working, *e.g.* by cold rolling, drawing, or pressing. Cold working involves mechanical treatment at atmospheric temp. so that the deformation hardens the steel; intermediate annealing may then be necessary to soften the steel

STEEL: MANUFACTURE & PROPERTIES

D. Lloyd Thomas, Lecturer in Metallurgy, Imp. Coll. of Science

This Encyclopedia contains articles on the various elements in steel, e.g. Carbon; Chromium; Iron; Molybdenum; Tungsten, etc. See also Bessemer Process; Casting; Iron and Steel Construction; Lattice; Metallurgy; Open Hearth Furnace; Pig Iron; Siemens Process; Tempering; Wrought Iron

Steel is an alloy of iron and carbon, containing up to 1.7 p.c. of carbon. When solid, it contains the carbon either as cementite (a compound of iron and carbon, Fe₃C), or in solid solution in the iron. Iron-carbon alloys of carbon content between 1.7 and 4.5 p.c. are classed as cast irons.

Steelmaking by melting and solidification was probably first developed by the Chinese, and it was probably about 350 B.C. that the earliest method of steelmaking used in India was first discovered. Following the Dark Ages, steel was made in the western world by heating solid iron in contact with charcoal at a yellow heat (about 1,100° C.). The charcoal carburised the iron, but only to a shallow depth. To overcome the sharp gradient in carbon content from the outside to the centre the bars were hammered down to give blister steel; this was broken into short lengths which were stacked on top of one another, heated to a welding heat, and re-forged to give shear steel. This contained as much carbon near the centre as it did near the out-

side, but it was still streaky owing to the unequal carburisation of the cemented bar.

About 1740, Benjamin Huntsman, a Doncaster clock-maker, rediscovered the art of steelmaking by melting and solidification, obtaining in this way a uniform carbon content throughout the steel. Steel made by the Huntsman method became known as crucible, or cast, steel.

The manufacture of steel begins with the smelting of iron ores to produce pig iron. Steels may be divided into two groups, tool steels and structural steels. To produce tool steel, carefully selected pig iron is converted into a very pure form of iron called puddled bar, and this is then alloyed with carbon and any other alloying elements in a simple melting process. The melting and alloying can be done in a crucible, as used by Huntsman, in an electric arc furnace, or in an electric induction furnace; the liquid steel is cast into moulds to give ingots for forging.

To produce structural steel, pig iron and steel scrap, in varying proportions, constitute the charge

Machining can be used for shaping either during or after the working operations.

The outstanding features of steel are its cheapness and its mechanical properties. No reliable record indicates when the phenomenon of hardening steel by quenching was first discovered. To this property of being hardened by quenching are due the excellent mechanical properties obtainable in steels.

Changes in Lattice Form

On being heated to about 900° C., iron changes its crystal lattice form from what is termed α -iron, which has a body centred cubic lattice, to γ -iron, whose lattice is face centred cubic; the reverse occurs on cooling through the critical temp. range. The low temp. form of iron, α -iron, dissolves only traces of carbon, the excess carbon usually forming a compound, cementite Fe_3C ; but γ -iron, the high temp. form, can dissolve appreciable amounts of this element. Therefore, when a steel is heated to above the critical range of temp., not only does the iron change from the α to the γ form, but the carbon which exists as cementite at low temps. dissolves in the new γ -iron crystals. If the steel now be allowed to cool slowly, the iron reverts to the α form, and the carbon is rejected or precipitated as stringers of cementite. This occurs when steel is fully annealed or normalised, i.e. heated to above its critical range, and cooled in the furnace in which it was heated (full annealing) or in air (normalising). Normalised and annealed steels are relatively soft. If, however, the steel is quickly cooled, say by quenching into cold water, the separation of the cementite does not have time to occur, and the carbon atoms are maintained dissolved in the α -iron crystals. These α -iron crystals, "super-saturated" with carbon, are called martensite, and to them is due the hardness of quenched steels. The higher the carbon content of the steel, the harder can it be made by quenching.

After a steel has been hardened by quenching, it is usually brittle, and tempering is advisable in order to impart toughness. Tempering involves reheating the hardened steel to a suitable temp., somewhere below 700° C. This treatment allows the α -iron crystals to reject the excess carbon as cementite in a fine, globular form, and the resultant tempered martensite structure of very hard,

finely dispersed cementite in a tough α -iron matrix develops the best combination of strength and toughness in the steel.

"Austempering" and "mar-tempering" are heat treatment processes in which the duplex hardening and tempering treatments are replaced by a single treatment of quenching the steel into a liquid bath held at a suitable temp. and retaining it in the bath for a suitable time before cooling to atmospheric temp.

While the properties of carbon steels which make it possible to harden and temper them are particularly useful, the drastic quenching that is necessary to harden the steel is often a serious limitation owing to the likelihood of distortion and cracking. However, the addition of special alloying elements, e.g. nickel and chromium, reduces the rate of cooling necessary to harden the steel, and, whereas carbon steels require cold water quenching, steels containing suitable alloying elements can be hardened by quenching in oil or even by cooling in air; hence terms like oil hardening and air hardening steels. The use of these steels reduces the dangers of distortion and cracking, makes it possible to harden larger sections of steel throughout, and gives improved resistance to shock. Carbon steels with ultimate tensile strength values exceeding about 50 tons per sq. in. tend to be brittle, but some alloy steels may still be reasonably tough with ultimate tensile strength values exceeding 100 tons per sq. in.

High Speed and Other Steels

In addition to improving mechanical properties at atmospheric temps., alloying additions also impart certain characteristic properties to steel. High speed steels, and stainless and heat resisting steels are examples. Carbon steels which have been hardened by quenching tend to lose their hardness on being heated to temps. in excess of about 200° C., but the addition of elements like tungsten and chromium markedly retards the rate of softening. This discovery has been of great value in the machining of metals, for, whereas carbon steel tools soften and lose their cutting efficiency if the temp. of the cutting edge exceeds about 200° C., high speed alloy steel tools retain their hardness and cutting efficiency up to red heat, which makes it possible for machining operations to be greatly accelerated. Carbon steels possess poor corrosion-resisting

properties both at atmospheric and elevated temps. The addition of chromium in excess of about 12 p.c. by weight, however, transforms steels from inferior to superior corrosion- and heat-resisting alloys, producing what are called stainless steels. These alloy steels are invaluable to engineers for use in particular conditions; but they are more expensive than carbon steels.

Steel, ALLAN GIBSON (1858–1914). English cricketer. Born Sept. 24, 1858, he was educated at

Allan G. Steel,
English cricketer

Marlborough and Trinity Hall, Cambridge. He played cricket for his school and university, being captain of Cambridge in 1880, and then of Lancashire. On nine occasions he played for England against Australia. Batsman and bowler, Steel scored 135 and 148 not out against the Australians, and in 1879 he bowled unchanged throughout both innings for the Gentlemen against the Players. In 1883 Steel became a barrister; in 1901 a K.C.; and in 1904 recorder of Oldham. He died June 15, 1914.

Steel, FLORA ANNIE (1847–1929). British novelist. Born at Harrow, April 2, 1847, her surname being Webster, she lived in Bengal after marrying a civil servant in 1867, and obtained a knowledge of

the country which is reflected in many of her novels.

A prolific writer, she married some of her work by sentimentality. Her best-known novels

included *The Potter's Thumb*, 1894; *On the Face of the Waters* (a tale of the Indian Mutiny), 1896; *The Hosts of the Lord*, 1900; *The Law of the Threshold*, 1924; *The Curse of Eve*, 1928. Her autobiography, *The Garden of Fidelity*, appeared in 1929, the year in which she died (April 12).

Steele, SIR RICHARD (1672–1729). British writer. Born in Dublin of mixed Irish and English parentage, he was educated at the Charterhouse and at Christ Church and Magdalen College, Oxford. Steele and Addison were friends at school, and the friendship continued during their university

days. Steele left without a degree in 1694, and, enlisting in the army, rose to the rank of captain in Lord Lucas's Fusiliers. To the astonishment of his brother officers the somewhat dissipated young soldier published a pious manual entitled *The Christian Hero*, 1701. The same year saw the production of his first play, a comedy entitled *The Funeral*; or, *Grief à la Mode*,

Rich Steele

From an engraving by W. Holt

followed later by two others. The moral tone which characterised Steele's plays was a complete contrast to the licence of the Restoration dramatists. His fourth and best play, *The Conscious Lovers*, was produced towards the end of his life in 1722.

The turning point in Steele's life came when in 1707 he was appointed gazetteer to the government. His work in this connexion soon suggested to his mind the possibility of publishing something on a broader basis than the formal official Gazette. The result was *The Tatler* (q.v.), the first number of which appeared April 12, 1709. From the 18th number he had the cooperation of his friend Addison, and the literary partnership continued when for some obscure reason *The Tatler* was discontinued, and two months later, March 1, 1711, *The Spectator* (q.v.) was started. This stopped in Dec., 1712, and was followed by other periodicals, including *The Guardian* and *The Englishman*, but all were short-lived.

In the meantime Steele had entered politics as a Whig, and was elected M.P. for Stockbridge in 1713, but a violent pamphlet by him, *The Crisis*, resulted in his

expulsion from the house. In 1715 he re-entered parliament as member for Boroughbridge, and was knighted. Steele made himself so obnoxious to the government over the Peerage Bill that he was deprived of the supervisorship of Drury Lane, which had been given him as a political reward. He died at Carmarthen, Sept. 1, 1729.

An interesting light is thrown on Steele's life and amiable character by the letters, published after his death, which he had written to his second wife. As a writer Steele is usually not as effective as Addison, but his prose has a careless strength and originality which that of his friend lacks, while his humour is more genial. See Addison, J.; *English Literature*; Prose. Consult Lives, H. R. Montgomery, 1865; Austin Dobson, 1888; G. A. Aitken, 1889; W. Connelly, 1934.

Steel Engraving. Art or process of engraving on steel. It is also used for an impression taken from an engraved steel plate. See Engraving.

Steelyard. Balance or weighing machine having a lever with two arms of unequal length. In a special sense the Steelyard was the name given to a community of foreign merchants, mostly German, who settled in London in the 13th century under the protection of charters. Among their early privileges was the safe keeping and repair of Bishopsgate, in return for which they were allowed free passage for their goods by that gate, and other valuable trading rights. They were dispossessed in 1460 of their tenancy of the gate owing to failure to keep it in repair. Attempts were made to oust the Germans from their other privileges, but they held their own with

Steelyard of Roman make, dating from the 1st century A.D.

the help of the Hanseatic League until the Merchant Adventurers successfully challenged German supremacy in the Baltic and elsewhere. In 1579 the Steelyard lost all rights but those in Thames Street, and on Aug. 4, 1598, the German merchants were forced to leave their

stronghold. See *Balance*; *Hanseatic League*; *Merchant Adventurers*; *Staple*.

Steen, JAN (1626-79). Dutch painter. Born at Leyden, he studied at Utrecht, and later under

Jan Steen,
Dutch painter

Jan van Goyen at The Hague. He worked alternately at Leyden, The Hague, Delft, and Haarlem, where he was influenced by Adrian Ostade, and his genre pictures, of which many are preserved at Amsterdam and The Hague, are highly prized. He is an outstanding painter of the manners and costume of the Dutch peasants of his day, delighting in depicting scenes of gaiety. He died at Leyden in 1679.

Steen, MARGUERITE. Contemporary writer. She was educated privately, and having been a schoolmistress during the First Great War, went on the stage. Joining Fred Terry's company, she toured the provinces for three years. Her first novel, *Gilt Cage*, appeared in 1927, and she achieved best-sellers with *Matador*, 1934; and *The Sun Is My Undoing*, 1941. She wrote also biographies of Sir Hugh Walpole, 1933, and Sir W. Nicholson, 1943; and, with D. Patmore, the play *French for Love*.

Steenbeek. River of Belgium, in the prov. of W. Flanders. Rising slightly W. of St. Julien, it flows N.W. and joins the St. Jean near Bixschoote. Between the rivers Kortbeek and Steenbeek much heavy fighting took place in the First Great War.

Steenbok (Dutch, stone buck). Small species of S. African antelope, *Raphicerus campestris*. It is distinguished by its upright horns about 4 ins. long, the presence of a gland-cavity in the skull, and the absence of lateral hoofs. Less than 2 ft. high, and of a tawny colour, it conceals itself well on the veld. It is sometimes called steinbock, a German name properly applied to the Alpine ibex, *Capra ibex*, of Europe. Pron. stainbock.

Steenwyk. Town of the Netherlands, in the prov. of Overijssel. It lies on the Steenwyker Diep, 8 m. by rly. N.W. of Meppel. There is active trade in local agricultural produce, and small industries in wood, tobacco, and tanning. In the neighbourhood are large pauper colonies engaging in agriculture,

Frederiksoord, Wilhelminasoord, and Willemsoord, each of about 450 houses, founded in 1816-17 by a charity organization. Pop. 8,900.

Steeple (A.S. *stypel*, a lofty tower). Comprehensive name for the tower, belfry, and spire of a church. See Belfry; Tower.

Steeplechasing. Horse-racing over obstacles. Its origin was indisputably a race on horseback from one church steeple to another which would be a landmark. "Hunting matches" were held in Queen Elizabeth's day—there is a reference, a few years later, to one at Huntingdon between Lords Haddington and Sheffield. The first steeplechase of which there is an authentic account took place in Ireland in 1752; this was a match between one O'Callaghan and Edmund Blake, the course, $4\frac{1}{2}$ m., lying between Buttevant church and S. Leger church. Alken's painting *The First Steeplechase on Record* is alleged to represent a race c. 1803 among cavalry officers stationed at Ipswich, but may have been an imaginative effort on the part of the artist.

Over country fenced and enclosed, steeplechasing has a recorded history from 1792, when three competitors rode an 8-mile course in Leicestershire. At Bedford in 1810 there was a 3-mile event over a made course with 8 built-up fences. An organized steeplechase meeting at St. Albans in 1830 was the precursor of similar meetings all over the country, and by 1866 there was racing under rules at 89 courses. The first Grand National (*q.v.*) was decided at Aintree on March 1, 1839, and was won by Lottery; the 18 runners included Conrad, ridden by Capt. Becher, whose name is commemorated in the Aintree water-jump, Becher's Brook.

Messrs. C. J. and E. Weatherby issued their first volume of *The Racing Calendar* in 1867; from the set of Grand National steeplechase rules therein have grown the existing rules issued by the National Hunt committee. Founded in 1863, this body corresponds in function to the Jockey Club (*q.v.*). The N.H.C. organizes annually its own meeting, first held at Market Harborough in 1860, and for many years now at Cheltenham; its principal event is the National Hunt Steeplechase, 4 miles, for horses that have never won, ridden by amateurs. The N.H.C. also sponsors point-to-point racing. Racing under N.H. rules is conducted at upwards of 50 courses,

including Aintree (Liverpool), Cheltenham, the "park" courses at Sandown, Kempton, and Hurst, Bogside, where the Scottish Grand National is held, Haydock Park, Manchester, and all over the Midlands. Hurdle races, an integral part of cross-country sport, are run over distances from $1\frac{1}{2}$ m. upwards. Flights of hurdles are distributed across racecourses in the proportion of 4 flights to every mile. These obstacles, smaller than fences, are taken at a much faster pace.

The steeplechasing season opens in Aug. and ends in May, but its most important period is from Oct. to April. The point-to-point season, organized by the various hunts, runs from Feb. to early May. All courses except Cheltenham are usually laid out side by side with flat race courses. A large proportion of the horses are owned by individuals who race on a modest scale and often train their own horses. Beginning as late 3-year-olds, the horses, mostly geldings, often continue their careers until late in life; winners at the age of 15 are not uncommon. A fair proportion of the fields consist of thoroughbreds, but the ideal jumper is bred from thoroughbred and hunter stock.

Steer. Word synonymous with bullock. It is applied to male beef cattle of any age.

Steer, PHILIP WILSON (1860-1942). British painter. He was born at Birkenhead, Dec. 28,

P. Wilson Steer,
British painter

1860; educated at Hereford cathedral school and Gloucester art school; and in Paris studied under Bouguereau and Cabanel. He exhibited at the R.A. in 1883, but soon became one of the first exhibitors at the New English art club (*q.v.*). Influenced during youth by Monet, he later adopted the impressionistic technique of Constable. Among the supreme artists of his time, primarily a landscape painter, he showed comparative indifference to the forms of objects, and was preoccupied with light and colour. His water-colours were specially praised. Steer's best-known works include Chepstow Castle, Painswick Beacon, and several fine paintings of the Severn Vale. Twelve canvases are at the Tate

Gallery, and a self-portrait (1906) is at the Uffizi Gallery, Florence. Assistant professor at the Slade school, Wilson Steer was awarded the O.M. in 1931. He died at Chelsea, March 21, 1942. Consult *Paintings of W. Steer*, R. Ironside and J. Rothenstein, 1944; *Life and Works*, D. S. MacColl, 1945.

Steerforth, JAMES. Character in Dickens's novel *David Copperfield*. David's old schoolfellow, a young man of ability, wealth, and good looks, he persuades Little Em'ly, Daniel Peggotty's niece, to elope with him and then abandons her. In the end he is drowned in a shipwreck off Yarmouth.

Steevens, GEORGE WARRINGTON (1869-1900). British journalist. Born at Sydenham, Kent, Dec.

G. W. Steevens,
British journalist

10, 1869, he was educated at the City of London school and Balliol College, Oxford, and became a fellow of Pembroke College. As editor of *The Cambridge Observer* and contributor to *The National Observer*, *Pall Mall Gazette*, and *Blackwood's Magazine*, he displayed brilliant literary power and originality. Joining the *Daily Mail* in 1896, he described the presidential election campaign in the U.S.A. in articles published as *The Land of the Dollar*, 1897. Other contributions appeared in book form as *With the Conquering Turk*, 1897; *With Kitchener to Khartum*, 1898; *The Tragedy of Dreyfus*, 1899. Sent to South Africa on the eve of the war, he was in Ladysmith when it was besieged, and died there of enteric fever, Jan. 15, 1900. His S. African articles were published as *From Cape Town to Ladysmith*. He also wrote *Monologues of the Dead*, 1896.

Stefanie. Lake of Africa. It lies mainly in Abyssinia, but partly in Kenya Colony, N.E. of Lake Rudolf. Its alt. is 1,830 ft.

Stefan's Law. The principle, discovered empirically by J. Stefan in 1879, and deduced from thermodynamic considerations by Boltzmann in 1884, that the rate of emission, E , of radiant energy from unit area of a black body is proportional to the fourth power of the absolute temperature T ; i.e.

$$E = \sigma T^4$$

where σ is Stefan's constant, equal to 5.7×10^{-5} erg cm.⁻² sec.⁻¹ deg.⁻⁴. See Radiation.

Stefansson, VILHJALMUR (b. 1879). Canadian Arctic explorer. Born Nov. 3, 1879, at Arnes, Manitoba, of Icelandic parentage, he graduated at Iowa university in 1903. In 1908 he was commissioned by the American museum of natural history to make an ethnological survey of the Central Arctic coast of America. Among his many discoveries on this expedition was that of the blond Eskimos of Victoria Land. In 1913 he was sent north by the Canadian government and, notwithstanding the loss of his vessel, the *Karluk*, pursued his exploration on sledge, and discovered Prince Patrick Land. He remained in the Arctic regions until 1918, having mapped large areas of coast. He published *My Life with the Eskimo*, 1912; *Stefansson-Andersen Expedition*, 1909-12, 1914; *The Friendly Arctic*, 1922. See Arctic Exploration.

an ethnological survey of the Central Arctic coast of America. Among his many discoveries on this expedition was that of the blond Eskimos of Victoria Land. In 1913 he was sent north by the Canadian government and, notwithstanding the loss of his vessel, the *Karluk*, pursued his exploration on sledge, and discovered Prince Patrick Land. He remained in the Arctic regions until 1918, having mapped large areas of coast. He published *My Life with the Eskimo*, 1912; *Stefansson-Andersen Expedition*, 1909-12, 1914; *The Friendly Arctic*, 1922. See Arctic Exploration.

Stegemann, HERMANN (b. 1870). Swiss historian. He was born at Coblenz May 30, 1870, and worked as a journalist in Zürich, Basel, and Berne. During the First Great War, he attracted international attention by objective comments on the war, published in the *Berne Bund*. After writing a history of the war, 4 vols., 1918-21, he was appointed professor of history at Munich university. He retired before Hitler's advent to power, and went to Zürich, where he again printed valuable discussion of the strategy of the Second Great War. As a novelist he wrote several Alsatian stories, e.g. *Daniel Junt*, 1905; *Die Krafft von Illzach*, 1913; *Die Herren von Höhr*, 1932; and an autobiography, 1930.

Stegocephalia (Gr. *stegein*, to cover; *kephalē*, head). Fossil amphibia distinguished as having an armour of bony scales. Found in strata from the Lower Carboniferous to the Upper Trias, they were capable of living partly on the land, possessing lungs. They include some of the largest amphibia known, and were mostly lizard-like in shape, with two pairs of limbs, long tail, and flattened head. See Reptile.

Stegosaurus. One of the great fossil dinosaurs. Ranging up to 30 ft. in length, with short limbs and powerful tail, it was remark-

able for the possession of a ganglion, controlling the nervous system, that was larger than the brain of the animal. See Dinosaur.

Stein, CHARLOTTE VON (1742-1827). Friend of Goethe. She was born on Christmas day, 1742, married the duke of Saxe-Weimar's master of the horse, became the intimate friend of Goethe, and is known to fame as the recipient of a long series of his letters. The intimacy was broken for a time by his marriage, but had been renewed before Charlotte died Jan. 6, 1827. Goethe's letters to her were first published during 1848-51, and the relationship of the two has given rise to a considerable literature. Consult Charlotte v. Stein, H. Düntzer, 1874; Goethe und Frau von Stein, E. Adler, 1887; Lotte in Weimar (fiction), T. Mann, trs. 1940.

Stein, GERTRUDE (1874-1946). American writer. She was born at Alleghany, Pa., Feb. 3, 1874, and educated at Radcliffe College, Harvard. She studied brain anatomy at Johns Hopkins university, but abandoned it, and settled in Paris in 1904, where she was a prominent figure in the world of art and letters, a patron of Picasso. She turned to writing, contributing to such coterie magazines as *Transition*. From the first her work was experimental; she played with words, forming sentence patterns that bore little or no relation to the use of words as the instruments of ideas. She had numerous imitators, but founded no school. She wrote *Three Lives*, 1908; *Tender Buttons*, 1915; *Autobiography of Alice B. Toklas*, 1933; *Wars I Have Seen*, 1946. With Lord Berners she evolved the ballet *Wedding Bouquet*. On July 27, 1946, she died in Paris.

Gertrude Stein, American writer

Stein, HEINRICH FRIEDRICH KARL, BARON VON (1757-1831). German statesman. Born Oct. 26, 1757, of an old family of imperial knights at Nassau, he studied law at Göttingen, and entered the Prussian service. He rose rapidly and did great work as minister for

commerce during the troubled years, 1804-06. In 1807 he was dismissed for urging the establishment of a responsible cabinet, but he resumed office as minister of the interior.

His wise reforms after the disaster of Jena conferred a large measure of self-government on the German towns, and he would have proceeded to a similar measure for the rural districts, but Napoleon divined that Stein was working for the restoration of the Prussian people to a great nation, demanded his dismissal as an enemy of France, and ordered his seizure. Stein then escaped to Bohemia. Fearing that his surrender might be demanded by Napoleon, he went in 1812 to St. Petersburg at the request of Alexander I. After the battle of Leipzig, 1813, he presided over the commission for the control of occupied territory.

At the congress of Vienna he worked hard to secure a consolidation of Germany, making great use of his influence over the tsar. He then retired into private life, occupying himself partly with the great collection of documents on German origins, *Monumenta Germaniae Historica*. Stein must be regarded as one of the makers of modern Germany. He died at his residence, Kappenberg, Westphalia, June 29, 1831. Consult *Life and Times*, Sir J. Seeley, 3 vols., 1878; Baron Stein, *Enemy of Napoleon*, C. de Grunwald, 1936.

Stein, SIR MARK AUREL (1862-1943). A Hungarian-born British explorer and writer. Born of Jewish stock at Budapest, Nov. 26, 1862, he was educated at Dresden, Vienna, and Tübingen universities, and went in 1888 to India as principal of Lahore Oriental College. In 1899 he became a British subject, and began a series of archaeological explorations in Turkistan, W. China, and Tibet. He was on journeys through Russian Turkistan and Persia during 1913-16, bringing back valuable additions to the British Museum and Delhi Museum. Other expeditions were to Baluchistan, 1926-28, and S. Persia, 1932-33. Sir Mark was knighted in 1912. His books included *Sand-buried Ruins of Khotan*, 1903; *Ancient Khotan*, 1907; *Serindia*, 1921; *On Ancient Central Asian Tracks*, 1933; *On*

Baron von Stein, German statesman

Old Routes of Western Iran, 1940. He died at Kabul, Oct. 26, 1943, bequeathing Oriental MSS. to the Indian Institute at Oxford, and a legacy to form the Stein-Arnold fund for exploration of India, China, and Persia.

Steinach, EUGEN (1861-1944). Austrian physiologist and biologist. Born at Hohenems, Vorarlberg, Jan. 27, 1861, he studied medicine at Vienna, and became professor and director of the physiological institute at Prague, and later director at the biological institute, Vienna academy of science. He wrote important works on the sex transformation of animals, and discovered the specific male and female sex hormones, but is best known for his experiments in human rejuvenation. These proved successful but for a limited period. His book about this method was published in 1920. He retired in 1930, and died in Vienna.

Steinbeck, JOHN ERNST (b. 1902). American novelist and playwright. Born Feb. 2, 1902, at Salinas, Calif., he attended his high school and spent a year at Stanford university before going into journalism. To this profession he returned in the Second

John E. Steinbeck,
American novelist

Great War as war correspondent of the Daily Express. His name was made, however, as a story-teller whose powerful sense of drama was second only to an intense concern with the social and economic struggles of the poorer classes. Cup of Gold, 1929, was his first book; Tortilla Flat came in 1935; more famous are Of Mice and Men, 1937; The Grapes of Wrath, 1939, set in the "bad lands" of the northern states, and awarded the Pulitzer prize for 1940; The Moon is Down, 1942, a tale of German-occupied Norway. These three were all dramatised and filmed. Steinbeck wrote Cannery Row, 1945; The Wayward Bus, 1947.

Steinitz, WILHELM (1837-1900). Bohemian chess-player. Born in Prague, May 18, 1837, he was educated at the institute of technology, Vienna. In 1866 he beat Anderssen in a chess match by 8 games to 6; in 1868 carried off the first prize in the British Chess Association handicap; and first prize in the London grand

tourney in 1872. At the chess congress in Vienna in 1873 he won first prize; and in 1876 defeated Blackburne in 7 consecutive games. Steinitz was for some time chess editor of The Field. In 1884 he settled in the U.S.A., where he published the International Chess Magazine from 1885 to 1891. One of the most scientific players who ever lived, he had a mental collapse and died insane at New York, Aug. 12, 1900.

Steinkirk or **STEENKERQUE**. Village of Belgium. It is 5 m. N.E. of Soignies. Here, Aug. 3, 1692, was fought a battle between the English and French. Louis XIV hoped to restore the French prestige by a decisive battle. William III made a surprise attack on the French army at Steinkirk, but an English victory was prevented by French reinforcements.

Steinmetz, CHARLES PROTEUS (1865-1923). German-American engineer. Born April 9, 1865, at Breslau, he emigrated at 24 to the U.S.A., where he eventually became consulting engineer to the General Electric co. at Schenectady. He died Oct. 26, 1923. Steinmetz specialised in research upon electric lighting, with particular regard to loss of power. He held patents for electric motors and generators, and wrote text-books on electrical practice.

Steinway, HEINRICH ENGELHARD (1797-1871). A German piano manufacturer. Born at Wolfshagen, in the Harz Mts., his real name was Steinweg. He became a musical instrument maker in Brunswick, and his pianos were ranked among the finest in the world. Leaving his eldest son in charge of the German business, he settled in New York with his other four sons in 1850, and three years later established the firm of Steinway and Sons.

Stela or **STELE** (Gr. *stēlē*, upright post). Upright slab bearing sculptural designs or inscriptions. The word is also applied to a prepared rock-surface similarly inscribed. The most numerous

examples and the oldest date from ancient Egypt, but stelas have also been found in Greece, Asia, and S. America. They are either funerary, mostly in tomb-chambers, or votive, usually dedicated by kings or eminent personages, in temples and public places. Sculptured and inscribed stelas were produced in ancient China, both funerary, such as the Han tombs in Shantung, and votive, such as the Nestorian tablet at Hsian-fu. A remarkable series has been unearthed on Maya sites in Guatemala and in the Zapotec city of Monte Alban in S. Mexico. They were usually set up on the terraces or the stairway bases of pyramidal mounds.

Stella (Lat., star). Name by which Sir Philip Sidney addressed Lady Penelope Devereux, afterwards Lady Rich, in his love sonnets, Astrophel and Stella. It was also given by Jonathan Swift to Esther Johnson.

Stellarton. Town of Nova Scotia, Canada, on the East River. Served by the C.N.R., it is the centre of a coal mining district, and has one of the thickest known seams of coal (37 ft.). Pop. 5,300.

Stella's Sea Cow, or **STELLER'S S.C.** Large marine mammal of the order Sirenia, with a length of some 20 ft. First observed in the Bering Sea about 1840, it was so pursued by Russian whalers that within 30 years it was extinct.

Stellenbosch. Town of Cape Province, S. Africa. It is 31 m. E. of Cape Town, with which it is connected by rly. The chief buildings are the Dutch reformed

Stela engraved with a charter of Nebuchadrezzar I, king of Babylon, c. 1120 B.C.
British Museum

Stellenbosch, Cape Province. View showing the English church

shurch, a theological college, and, in addition to the university, colleges of various kinds. There are a number of 18th century houses in the Dutch style. Around are vineyards and fruit farms and in nearby streams considerable alluvial tin deposits have been worked. After Cape Town the oldest town in S Africa Stellenbosch was settled in 1680. It was named after a certain Simon van der Stell and his wife, whose name was Bosch. During the S. African War Stellenbosch was a British base. Officers removed from their commands at the front were frequently sent there, and so the term to be stellenbosched came into use for those who were regarded as unfit for their duties. Pop. (European), 7,474.

Stellenbosch, UNIVERSITY OF. Educational centre founded in 1918 as one of the five universities of South Africa. It took over Victoria College, Stellenbosch, and is governed by a council, senate, and convocation. There are, on the average, some 2,000 students in residence.

Stelvio Pass. Alpine pass in Italy. It is on the great highway from Milan to Innsbruck, connects Meran and the valley of the Upper Adige in Tirol with Bormio in

Stem. In botany, the axis of a plant, that which bears the flower, leaves, and root. It may be erect,

Sten Carbine. Diagram showing parts and explaining the mechanism of the automatic weapon used in the Second Great War

climbing, creeping, or pendulous, or may extend underground, in which case it differs from the roots in its capacity for bearing leaves. Though in shape usually cylindrical, it is sometimes triangular (water-plantain), square (Labiateae), or leaf-like (Phyllocactus). In early growth, a stem is usually soft and green, but later often becomes hard and woody, as with the trunks of trees. In trees, shrubs, and certain other plants, the stem persists all the year round; in herbaceous plants it dies down in the autumn, but the plant may have an underground stem, e.g. a rhizome, bulb, corm, or tuber. (See Botany; Cytology; Phloem; Plant.)

The word is also used for anything that resembles a stalk or

Britain and to utilise the large quantities of Italian 9 mm. ammunition captured in the Western

Desert. Suitable for mass production, the Sten has only 51 parts, of which only the bolt must be machined to precision limits; wherever possible joints are rough-welded and most of the manufacturing

processes can be carried out by unskilled labour. Fed from a box magazine, the Sten has an effective range of 200 yds., and a maximum rate of fire of 500 r.p.m.,

Sten Carbine. The correct way to hold this weapon when firing from the shoulder

though it can be adjusted to fire single shots. The Sten may be fired from either shoulder or hip. In the Second Great War over 3,000,000 Stens were used by the Allied regular armies, the Home Guard, R.A.F. Regiment, parachute troops, and commandos, or dropped by parachute to partisans in the occupied countries.

Stencilling (Old Fr. *estinceller*, to powder with stars). Printing, on paper or other prepared surface, of a pattern by means of a thin sheet of metal, cardboard, etc., pierced with spaces. When the ink or colour is brushed over the whole surface, it falls into the spaces and is excluded by the sheet elsewhere. Stencilling was the earliest method of printing coloured wallpapers, and is used in various forms of surface decoration.

Stendal. Town of E. Germany. In the *Land* of Saxony-Anhalt, it is situated on the Uchte, 60 m. W. of Berlin. The chief buildings are the old cathedral, S. Mary's church (1435-47), and the town hall (15th-16th century). The cathedral is a Gothic building dating from 1188-1250, and restored in the 19th century; its cloisters were used for a museum. There are remains of the town's fortifications. A railway junction, Stendal had manufactures of railway stock, textiles, tobacco,

Stelvio Pass. Windings of one of the highest carriage roads in Europe

the valley of the Adda, and carries the highest carriage road in Europe, the summit being 9,055 ft. in altitude. The road was built by the Austrians, 1820-24.

Stem. In philology, that part of a word which remains when the inflexional endings are removed. It is either identical with the root or formed from it by means of a suffix. Stems formed directly from the root are called primary; those added to an existing stem are secondary. See Philology; Root.

stem, such as the stem of a pipe. The stem of a feather (*q.v.*) is its main stalk. In music, it is the stroke drawn from the head of a note. In shipbuilding, it is the upright bar of iron or piece of timber at the fore end of a vessel, to which are attached the forward ends of the strakes. See Ship.

Sten Carbine. Light automatic infantry weapon. It was developed early in the Second Great War to meet the shortage of automatic firearms in Great

and leather. Founded in the 12th century, it was the capital of the old mark of Brandenburg, the residence of its rulers, and the seat of a bishop. A printing press was set up here in 1488. After the Second Great War it came within the Russian zone of occupation. Pop. 38,000.

Stendhal. Pen-name of Marie Henri Beyle, French novelist (1783-1842). He was born at Grenoble, Jan. 23, 1783. He

obtained a post in the ministry of war, witnessed the battle of Marengo, and then enlisting, rose to be adjutant to Michaud. During 1806-14 he held a

place in the commissariat, taking part in the campaign of 1812. From 1815 to 1821 he lived at Milan. Beyle then returned to Paris, and, having been consul at Trieste and Civit  Vecchia, 1830-41, died in Paris, March 23, 1842.

Stendhal, who wrote three novels, *Armance*, 1827; *Le Rouge et le Noir*, 1831; and *La Chartreuse de Parme*, 1839, notable for its account of the battle of Waterloo, may be regarded as the creator of that modern novel of psychological analysis which Bourget and d'Annunzio did so much to popularise. His critical works include *Histoire de la Peinture en Italie*, 1817; *De L'Amour*, an acute and cynical analysis of love; and *Racine et Shakespeare*, 1823, a defence of romanticism. *Consult* Lives, E. Rod, 1892; F. C. Green, 1939.

Stenness, STONES OR. Megalithic stone circles near Maeshowe, Orkney (*q.v.*). A 30-foot moat encloses 2½ acres, within which stands the Ring of Brogar, 342 ft. across, the largest cromlech in north Britain. Of the 60 original red-sandstone blocks, 13 are still erect, 23 lie prostrate. Of a smaller circle, once of 12 stones, two are erect, and one (19 ft.) lies near a ruined dolmen. Outside this stood the perforated Stone of Odin, mentioned by Scott in *The Pirate*.

Stenography (Gr. *stenos*, narrow; *graphein*, to write). System of writing in which words are expressed by abbreviations or by a system of characters taking less time to write than the normal alphabet. See *Shorthand*.

Stenotyping. Mechanical process of making shorthand notes.

This is done by means of a machine called a stenotype, so constructed that any one or any combination of letters or numbers can be printed at one time on one line of a strip of paper automatically fed into the machine. By using contractions for long words, it is possible to print very rapidly, and substitute printed characters for the normal shorthand devices.

Stentor. In Greek mythology, the herald of the Greeks in the Trojan War. He was famous for the loudness of his voice, which was said to equal that of thirty men. The English word stentorian is derived from his name.

Step. Word used in a number of senses. It is the rung of a ladder or part of a stairway. In machinery, a series of offsets or parts resembling the steps of stairs are called steps. It is also the name for a bearing at the bottom of a vertical shaft. In seamanship it is a frame of wood or metal intended to receive an upright shaft, *e.g.* the framing at the bottom of a mast, which is said to be stepped.

In combination the word is used in such expressions as stepfather, etc., indicating relationship by marriage and not by blood.

A step gauge is a compound plug gauge consisting of a number of short cylindrical gauges of graduated diameters on the same axis.

Stepanakert. Capital of Nagorno Karabakh (*q.v.*), a province of Azerbaijan S.S.R.

Stephanome (Gr. *stephanos*, wreath; *nomos*, rule). Meteorological instrument for measuring the size of haloes, etc. Invented by P. G. Tait, it consists of a graduated rod with a sliding bar with an outer and inner pair of points. These points are made to coincide with the ends of the diameter of a halo being measured.

Stephen. Saint and first Christian martyr. After the death of Jesus he joined the followers of the new faith in Jerusalem. One of the seven chosen to look after the poor (Acts 6), he was a man "full of faith and the Holy Ghost," and took a prominent part in controversy. His words made his enemies angry, and he was brought before the council. The speech given in Acts 7 did not save him, and he was stoned to death. S. Stephen's Day is Dec. 26.

Stephen (c. 1097-1154). King of England. A younger son of Stephen, count of Blois, and Adela, a daughter of William the Conqueror, he lived in boyhood at the court of his uncle Henry I. Although he had sworn to help

Henry's daughter, Matilda, to obtain the throne on her father's death, when that event occurred, Dec. 1, 1135, Stephen put himself forward and was crowned, his brother, Henry, bishop of Winchester, being one of his chief supporters. The reign was a period of anarchy, due in part to Stephen's subservience to the great barons, and in part to his folly in imprisoning the bishops who controlled the administration. Rebellions broke out, and in 1139 Matilda appeared to claim the throne. In 1141 Stephen was captured, but soon he was free again and the civil war continued for 12 years. When Matilda left the country her place was taken by her son, Henry, and in 1153 the treaty of Wallingford provided that he should succeed Stephen, who died Oct. 25, 1154. This unsuccessful ruler is in character one of the most attractive kings of England. He married Matilda, countess of Boulogne. His elder son, Eustace, predeceased him in 1153; the younger, William, called the Clito, appeared later in arms against Henry II.

Stephen (977-1038). King of Hungary and saint. The son of Geza, duke of Hungary, he changed his name from Wajk to Stephen at his conversion and baptism in 997. By marriage with the Bavarian princess Gisela he secured German aid in christianising Hungary. In 998 he took the title of king, and in 1001 received from Pope Sylvester II the famous iron crown. His reign was spent in wars against the heathen, and in 1030 he repelled an invasion by the emperor Conrad II. He died Aug. 30, 1038, and was canonised in 1083.

Stephen. Name of nine popes. Stephen I, pope 254-257, decided against S. Cyprian of Carthage that baptism by heretics was valid. Stephen II is noticed below. Stephen III, a Sicilian monk, pope 768-772, was elected by the overthrow of two lay claimants to the papacy. Stephen VI was strangled after reigning six months, 896-897. The election in 752 of a Stephen who died before his consecration has caused confusion in the numbering; many lists count the unconsecrated pope as Stephen II, and thus make ten Stephens.

Stephen II (d. 757). Pope from 752 to 757. A Benedictine monk of Rome, his reign saw the establishment of the papal monarchy. He obtained the help of Pepin the Short, the Frankish king, against Aistulf, king of the Lombards, who sought to conquer all Italy, and on

"Stendhal,"
French novelist

Aistulf's death, 756, he supported Desiderius in his claim to the Lombard crown. Desiderius retained Bologna, Imola, and other cities, but Stephen consolidated papal rule over Ravenna and the cities formerly under the Byzantine exarch. He died April 26, 757. *Consult* Beginning of the Temporal Sovereignty of the Popes, L. M. O. Duchesne, 1908.

Stephen, SIR JAMES FITZJAMES (1829-94). British judge and author. Born at Kensington, March 3, 1829, a son of the historian, Sir James Stephen (1789-1859), he was educated at Eton, King's College, London, and Trinity College, Cambridge. Called to the bar in 1854, he helped to codify Indian law, 1869-72, and was a judge of the high court from 1879 to 1891, when he received a baronetcy. He wrote for *The Saturday Review* and *The Pall Mall Gazette*, while his works on legal subjects include *Digest of the Law of Evidence*, 1876 (12th ed. with additions, 1947), and *History of the Criminal Law of England*, 1883. He died at Ipswich, March 11, 1894.

Stephen, SIR LESLIE (1832-1904). English man of letters. Born in London,

Sir Leslie Stephen,
English man of letters
Beaconsfield

but steadily developed an agnostic attitude and in 1875 relinquished them. From 1865 he was contributing to *The Saturday Review*, the newly founded *Pall Mall Gazette*, and *The Cornhill Magazine*. His connexion with the last-named, of which he became editor in 1871, led to his being asked by George Smith (*q.v.*) in 1882 to edit *The Dictionary of National Biography*. Knighted 1902, he died Feb. 22, 1904.

His works include *Hours in a Library*, 1874-79; *History of English Thought in the 18th Century*, 1876; *The Science of Ethics*, 1882, in which are summed up his philosophic and religious

conclusions; *An Agnostic's Apology*, 1893; biographies of Johnson, Pope, Swift, George Eliot, and Hobbes in the *English Men of Letters* series. His mountaineering activities are reflected in *The Playground of Europe*, 1871. Among his friends were Stevenson and Henley. Stephen's daughters were Vanessa Bell and Virginia Woolf. *Consult* Life and Letters, F. W. Maitland, 1906.

Stephens, JAMES (c. 1825-1901). Irish agitator. A Kilkenny man, he was deeply implicated in the disturbances of 1848. He took refuge in Paris and in 1853, with John O'Mahoney, founded the Irish Republican Brotherhood, or Fenian Society (*q.v.*). In 1865 he attempted a rising in Ireland, but it failed, and he was imprisoned in Dublin Castle, from which he escaped and fled to America. Subsequently he lived in retirement in France and Ireland, dying at Blackrock, April 29, 1901.

Stephens, JAMES (b. 1882). Irish poet. As a Dublin youth he worked in a lawyer's office and became an ardent nationalist whose writing was steeped in Celtic legend. Publication in 1912 of *The Crock of Gold* made his name, and there followed *Irish Fairy Tales*, and *Deirdre*, both 1923; *In the Land of Youth*, 1924; *Kings and the Moon*, 1938. A friend of Yeats and others in the Irish literary revival, Stephens was also a critic and broadcaster.

Stephenson, GEORGE (1781-1848). British engineer. Born at Newcastle-upon-Tyne, June 9, 1781, the son of a colliery fireman, he became assistant to his father at the age of 14, learning to read and write at a night school. In 1808 he contracted with two others to work the engines of Killingworth pit, and he dismantled his engine once a week until he was thorough master of its construction. In 1812 he was appointed engine-wright to the colliery, and in 1815 invented a safety lamp for miners, which brought him a grant of £1,000.

The rapid progress of the steam engine directed Stephenson to the work with which his name is always associated. Receiving financial assistance, he built his first locomotive in 1814; this could haul 30 tons at 4 m.p.h. In

1815 he made improvements in its construction, including the use of the steam blast. The failure of steam locomotives to work on any real gradient on the roads turned Stephenson's attention to the construction of railroads, and in 1819 he superintended the laying down of a short line at Hetton Collieries, and in 1823 the line between Stockton and Darlington.

The first locomotive, built by Stephenson, to use this line reached a speed of 16 m.p.h. and weighed eight tons. In 1826 he began the construction of the Liverpool and Manchester rly., and in 1829 he built the Rocket (*q.v.*). He was appointed chief engineer to a number of railways, and was consulted on practically every important line constructed. In 1847 Stephenson became president of the Mechanical Engineers. The most modest of men, he died Aug. 12, 1848, and was buried at Chesterfield. *See* Locomotive; Steam Engine; *consult* Life, S. Smiles, 1864.

Stephenson, ROBERT (1803-59). British engineer. Son of George Stephenson, he was born at Willington Quay,

near Newcastle-upon-Tyne, Oct. 16, 1803. He helped his father to survey the Stockton and Darlington rly., 1821, and then entered Edinburgh university. After George Richmond

After George Richmond

Poor health compelled him to go abroad, and in 1824 he accepted an offer to superintend gold and silver mines in Colombia. On his return in 1827 he assisted his father in building the famous Rocket, to which he suggested many improvements, and constructing the first railway into London, that from Birmingham, 1833-38. The Menai tubular bridge, the Victoria bridge over the St. Lawrence at Montreal, and many others were built by Stephenson. He was elected M.P. for Whitby, 1847, and represented the town till his death. President of the Institute of Civil Engineers, 1856-57, he died Oct. 12, 1859, and was buried in Westminster Abbey. His cousin George Robert Stephenson (1819-1905) also built bridges. *See* Locomotive.

Stepney. Met. bor. of the co. of London. It has Bethnal Green on the N., the City and Shoreditch W., Poplar E., and extends on the S. to

George Stephenson,
British engineer
After Briggs

the Thames. It contains the Tower, the Mint, St. Katherine's, London, and Regent's Canal docks, Shadwell Basin, and comprises

Stepney arms

Limehouse, Mile End, White-chapel, and St. George's. In the church of S. Dunstan, rebuilt by Wren, were buried Sir Thomas Spert, founder of Trinity House (*q.v.*), and Sir Henry Colet, father of Dean Colet, sometime vicar of Stepney. There are many charitable institutions, including Dr. Barnardo's Homes (*q.v.*) and the London Hospital. Three M.P.s were elected until 1950, and thereafter one. Since 1895 Stepney has given its name to a suffragan bishopric. The exceptional damage suffered by this borough in air raids, 1940-41 and 1944-45, reduced its pop. by about half to 109,000 but offered opportunity for drastic re-planning.

Stepniak, SERGIUS (1852-95). Russian writer and revolutionary leader. He was born in southern Russia of noble descent, his proper name being Sergius Michaelovitch Kravchinsky. When he was little over twenty he was arrested owing to his association with a known group of Nihilists. Before he was thirty he left Russia, and lived first in Switzerland and later in England, where he became prominent as a writer and lecturer. His best known works were *Underground* Russia, 1882; *The Career of a Nihilist*, a novel, 1889; and *King Stork and King Log: A Study of Modern Russia*, 1896. He was killed at a rly. level crossing at Chiswick, Dec. 23, 1895.

Sergius Stepniak,
Russian writer

Steppe. Vast grassy plain of S.E. Russia and W. Siberia. Owing to the little rainfall, or, in some cases, to the porous character of the soil, trees are not found except along the banks of rivers, or where there are permanent supplies of moisture. Grasslands like the steppes are found in similar positions in other continents, *i.e.* in interior regions of temperate latitudes, where the rainfall is light and mainly confined to spring and early summer. See *Pampas*; *Prairie*; *Siberia*.

Sterculiaceae. A Family of herbs, shrubs, and trees. Natives of tropical and sub-tropical regions, they have mostly alternate leaves and regular flowers. They are mucilaginous, and the bark of the woody species contains bitter and astringent principles useful in medicine. *Sterculia tragacanthae* yields gum tragacanth. The order also includes cocoa (*Theobroma cacao*), kola (*Cola acuminata*), etc.

Stère (Gr. *stereos*, solid). Unit of cubic measurement in the metric system. It is one cubic metre, and equals a kilolitre, or 35·3145 cubic feet. It is used in measuring firewood. See *Metric System*.

Stereochemistry (Gr. *stereos*, solid). Branch of chemistry dealing with the arrangement in space of the atoms within the molecule, and especially with those kinds of isomerism—known as stereoisomerism—which depend upon differences in this arrangement. Pasteur first called attention to the existence of compounds, *e.g.* tartaric acid, which are known in different forms, that, although alike in chemical and most physical characters, exhibit a difference in optical properties.

Stereochemistry has been of special importance in connexion with the study of the sugars and allied compounds, and it has also explained diverse phenomena in chemistry (*q.v.*).

Stereoscope (Gr. *stereos*, solid; *skopein*, to view). Optical instrument which presents to each eye separately a flat image, either a drawing or a photograph, of an object as seen by the respective eyes, and so producing the effect of relief. The instrument was in-

Stereoscope. Open form of the optical instrument, showing how two almost identical images are exposed

vented by Wheatstone in 1838, and the separate pictures were reflected by mirrors. The use of two prism eyepieces was due to Brewster, 1849, and, as modified by making the prisms in the form of sections of convex lenses, has been generally adopted. The open stereoscope was due to O. W. Holmes in 1861.

In making stereoscopic views by photography, two negatives are made simultaneously by means of a camera which has two lenses placed a few inches apart, or by shifting the camera approximately 2½ in. to left or right in the same plane between two successive exposures. The pictures are transposed in printing, the positive from the left-hand photograph being placed on the right and vice versa. Stereoscopic pictures may be viewed as positive prints by reflected light or as transparencies by transmitted light. The latter gives the best effect, especially with coloured pictures.

Stereotyping. Method of reproducing for printing a surface of movable type or relief printing blocks. Two operations are involved, the moulding of the matrix from the type, and the casting of the stereotype from the mould. It is executed by making in plaster of Paris or papier-maché by extreme pressure heavy impressions of the surface of a forme containing type or illustrations, or both, such as a page of this Encyclopedia, and a mould or matrix is thus secured into which molten metal is poured, producing a new metal surface with characters in relief identical with the original. Many printing plates can be produced from one papier-maché mould, and by means of this process huge editions of newspapers, produced within the space of an hour or two, become possible.

While the principle of making stereotypes for ordinary flat bed printing and newspaper printing is the same, with the latter the cast, instead of being a plane with the upper surface in relief, is produced in semi-cylindrical form or crescent-shaped, and with a periphery corresponding to the cylinder of the newspaper rotary printing press. See *Electrotype*; *Forme*; *Linotype*; *Lithography*; *Monotype*; *Newspaper*; *Printing*.

Stereum hirsutum. Leathery fan-shaped fungus belonging to the family Thelephoraceae. It is

Stereum hirsutum. Upper side of the fungus that grows upon the branches and trunks of trees

common on the trunks and branches of trees, and is of a dull yellow tint, becoming paler and greyish. The faintly zoned upper side is covered with a coarse velvet, and the bright coloured underside is smooth. The upper side may be almost wholly attached to the tree, only a portion of the margin being free and growing out; occasionally it may be growing quite free and assuming a funnel shape. The spores are produced on the smooth under surface. Its effect on oak timber is to produce the condition known as "piped" or "flywood."

Sterilisation (Lat. *sterilis*, barren). Term used in bacteriology and chemistry for the process of destroying bacteria.

The sterilisation of food forms an important part of its preparation for human consumption. Water can be sterilised by boiling or distillation, and milk by boiling or exposing to superheated steam. Boiling or exposing milk to great heat alters its character and its food value, and its sterilisation is better carried out by pasteurisation (*q.v.*). Milk can also be sterilised by the addition of antiseptic substances, *e.g.* boric acid; and has been sterilised by electricity and by supersonic vibrations.

In surgery it is important that all instruments and materials used in operating shall be sterilised. Boiling in water, the use of the autoclave (*q.v.*) in which steam under pressure is used, and the use of disinfectants and antiseptics, *e.g.* phenol and iodine, are the chief means of sterilisation in surgery. Instruments plunged in an open flame are sterilised.

All bacteria can be killed by heat, especially moist heat, but many will survive the greatest cold. For the study of bacteria it is necessary to obtain a pure culture upon which they can be grown artificially. Such substances are sterilised by heat. See Bacteriology; Food Preservation.

Sterilisation. In eugenics, the rendering incapable of reproduction of human beings or animals without interfering with their sexual life. In the male it is achieved by tying off the sperm-conducting tubes (in contrast to castration, where the testes are removed, and the animal thereafter has no sexual life). Sterilisation is sometimes practised with valuable animals when it is desired that they should not sire from unchosen stock, but is generally performed for commercial reasons. It is little practised in

medicine, though many physicians advocate its application to prevent the reproduction of individuals with transmissible flaws. Sterilisation of females is carried out by tying off the fallopian tubes; this is done in women when for some medical reason they should not become pregnant.

Sterility. Inability of animals and plants to produce offspring. Many reasons have been assigned for this defect, but apparently it is often due to changed conditions of existence, as with wild animals in zoological gardens; though distinct families of animals exhibit considerable differences in this respect. As a rule, hybrids resulting from the pairing of distinct species are sterile; on the other hand, when the parents are of different races or varieties of the same species, the hybrid shows greater fertility. Many plants are sterile when fertilised with their own pollen, while producing seed abundantly under the influence of pollen conveyed from another individual of the species; other varieties are habitually fertile when self-pollinated.

Sterling. Term used in three senses: (a) To describe 22 carat gold, *i.e.* a mixture of 22/24 pure gold and 2/24 alloy, and 18½ carat silver, *i.e.* a mixture of 37/40 pure silver and 3/40 alloy; these are the standard gold and silver formerly used in British coinage; (b) as an adjective, to indicate a degree of excellence comparable to that of sterling gold and sterling silver; and (c) as a noun, to denote the British pound, and as an adjective, to distinguish things pertaining to the British pound (for example, sterling exchange, sterling loan, etc.). The name may be derived from the Easterlings, German merchants who settled in London in the 14th century and circulated coins rather better than those generally used; or from an early silver penny—called the sterling because it bore starlings as a device and was noted for its intrinsic worth.

Sterling Area. Term applied to countries which normally pay for imports by drafts on British banks, and make available to British banks dollars and other non-sterling currencies received for goods exported. In September, 1948, the sterling area or sterling bloc proper included the U.K., the dominions of Australia, New Zealand, S. Africa, and Eire, Burma, Iraq, Iceland, Ceylon, Hong Kong, Malaya, the African colonies, dependencies, and man-

dated territories, Trinidad, Bermuda, British W. Indies, and certain other mandated territories. In these countries there was very close cooperation through the bank of England in all matters relating to payments to and from other areas. In addition, a number of other countries, including India, Egypt, Brazil, Argentina, Uruguay, Iran, the Belgian Netherlands, and the Italian territories, agreed to receive payment in sterling for stated amounts of their total exports. One effect of the war was to increase the "sterling balances" of the members of the pre-war sterling group, which included India, from about £200 millions to more than £2,650 millions, and the sterling balances of other countries to £618 millions.

Sterling, ANTOINETTE (1850-1904). American singer. She was born at Sterlingville, New York,

Antoinette Sterling,
American singer

Jan. 23, 1850, and studied singing in New York and under Marchesi, Viardot-Garcia, and Manuel Garcia, returning to New York in 1871 and soon becoming known as a leading contralto concert singer. She made her first London appearance in 1873, and thereafter remained in England, though touring the U.S.A., 1875, and Australia, 1893. Her dramatic sense made her a powerful ballad singer, and among her most famous songs were *The Lost Chord* (Sullivan), *The Better Land* (Cowen), and *The Sands of Dee* (Hullah). Married to John Mackinlay, 1875, she died at Hampstead, Jan. 9, 1904.

Sterling, JOHN (1806-44). Scottish author. Born July 20, 1806, at Kames Castle, Bute, the son of Captain Edward Sterling (1773-1847), who became a leader writer on *The Times*, he was educated at Glasgow university and Trinity College, Cambridge.

John Sterling,
Scottish author
After Delacour

In 1828 he became for a time part proprietor of *The Athenaeum*. Soon after his marriage in 1830 he had the first attack of the lung trouble which eventually proved fatal. In search

of health he went to St. Vincent as manager of a sugar plantation, but after fifteen months he returned to England, took orders, and for a short time was a curate. He died Sept. 18, 1844. His *Essays and Tales* were published in 1848, but he would be forgotten but for the biography by his friend Carlyle.

Stern. Rear part of a vessel or boat. It meant originally the helm or tiller, the word being related to steer. *Pron.* as spelt. See Ship.

Stern, DANIEL (1805-76). Pseudonym of Marie Catherine Sophie de Flavigny. Born at Frankfurt, Dec. 31, 1805, she married in 1827 the Comte d'Agoult, but deserted him for Liszt. the famous composer, to whom she bore three daughters. The eldest child married Emile Ollivier, and the youngest married Hans von Bülow and subsequently Wagner. Daniel Stern's best work is *Moral Sketches*, published in 1849. She died March 5, 1876. See *Lettres à Daniel Stern*, G. Mazzini, 1872.

Stern, GLADYS BRONWYN (b. 1890). British writer. Born of Jewish descent in London, June 17, 1890, she was educated in Germany and Switzerland, and studied at the R.A.D.A. Her first published novel, *Pantomime*, appeared in 1914, and she achieved fame with *Tents of Israel*, 1924 (a brilliant study of a Jewish family) which, in collaboration with Frank Vosper, she dramatised for Mrs. Patrick Campbell, as *The Matriarch*, 1929. A prolific writer of novels, short stories, and film scenarios, her other works included *A Deputy Was King*, 1926; *Debonair*, 1928 (dramatised, 1930); *Mosaic*, 1930; *Oleander River*, 1937; *The Young Matriarch*, 1942. She collaborated with Sheila Kaye-Smith in *Talking of Jane Austen*, 1943.

Stern, OTTO (b. 1888). German-born American physicist. He was born at Sorau, Feb. 17, 1888, and educated at Breslau university. Successively lecturer in

physics at Zurich and Frankfurt, he became professor at Rostock, 1921-22 and at Hamburg, 1923-33. Of Jewish stock, he was attacked by the Nazis, and he eventually went to the U.S.A., as professor at the Carnegie institute of technology at Pittsburgh. As a result of his work on extensions of Planck's quantum theory, he was awarded the Nobel prize for physics, 1943.

Sterne, LAURENCE (1713-68). British humorous author. He was born Nov. 24, 1713, at Clonmel, Tipperary, and on his father's death in a duel was sent by relatives to Jesus College, Cambridge, where he graduated in 1736. Ordained in that year, he received the living of Sutton-in-the-Forest, near York, remaining for 20 years. When he was 45, in 1759, the first portion of *The Life and Opinions of Tristram Shandy* appeared. The book was an immediate success, and Sterne proceeded to London to enjoy the fame it had brought, to which his audacious wit was to add. Presented to the

though this too often degenerates into sentimentalism. Sterne's works were ed. in 6 vols., G. Saintsbury, 1894. His letters, ed. L. P. Curtis, appeared in 1935. The best lives are by P. Fitzgerald, rev. ed. 1896, and W. L. Cross, 3rd ed. 1930, while there is a sketch in P. Quennell's *Four Portraits*, 1945. See *English Literature*; *Novel*; *Tristram Shandy*.

Stern Gang. Terrorist band operating in the Middle East. It was formed in 1940 by Abraham Stern (d. 1941) from extreme elements of Irgun (*g.v.*) after that organization had made a wartime truce with Great Britain. The Stern Gang, which sometimes styled itself the *Fighters of Freedom for Israel*, co-operated with the Axis and by acts of violence and sabotage attempted to hinder Allied war plans in the Middle East. It executed most of the terrorist acts in Palestine, 1942-47; two members, condemned and executed for the crime Jan., 1945, murdered Lord Moyne, resident minister in the Middle East in Cairo, Nov. 5, 1944. British troops were murdered, and bomb outrages carried out. After the withdrawal of the British, the Gang extended its hostility to U.N. representatives, and proclaimed its responsibility for the murder of Count Bernadotte, U.N. mediator, Sept. 17, 1948. The Israeli govt. outlawed the organization, arrested some 200 members, and on Sept. 30 captured its leader, Nathan Yellin, and his deputy. Sentenced, Feb. 10, 1949, to 8 and 5 years' imprisonment respectively, they were immediately freed under an amnesty, and Yellin took his seat in the constituent assembly as the only representative of the *Fighters' party*, into which the Stern Gang had been transformed.

Sternhold, THOMAS (c. 1500-49). English versifier of the Psalms. A small landed proprietor in Hampshire, he is believed to have been born at Southampton, and educated at Christ Church, Oxford, and was groom of the robes to Henry VIII. He was the author, with John Hopkins (d. 1570), of metrical versions of the Psalms, which enjoyed great popularity. The first edition, c. 1547, contained 19 psalms, and the second, 1549, had 37 by Sternhold and seven by Hopkins. The complete volume, 1562, had no rival until the versions of Tate and Brady. Sternhold died Aug. 23, 1549.

Sternum. Bone in front of the chest connecting the ribs. See *Breast-bone*; *Rib*.

"Daniel Stern,"
German author
From a sketch by
Claire-Christine

After Sir Joshua
Reynolds

perpetual curacy of Coxwold, he proposed to himself a life of literary activity, but dissipation soon affected his health, and periods of travel were necessary for recuperation. He visited Paris, and in its salons was lionised as he had been in London. His foreign peregrinations are reflected in later volumes of *Tristram Shandy*, of which the last came out in 1767, and in *Sentimental Journey* through France and Italy, published three weeks before his sudden death in London, March 18, 1768.

Sterne's humour, though frequently indecent, is of a high order, and finds expression in the character-drawing of Uncle Toby, Corporal Trim, and the Widow Wadman. He is also a master of pathos,

G. B. Stern,
British writer

Steroid. Generic term for any one of a group of chemical compounds including the sterols, bile acids, heart poisons, sex hormones, and saponins. Steroids are regarded as derivatives of the hydrocarbon cyclopentanoperhydrophenanthrene. The steroid group includes the hormones oestrogens or true ovarian hormones, progesterin, the androgens or testicular hormones, and the hormones of the suprarenal cortex.

Stertor OR STERTOROUS BREATHING. Sound resembling snoring, caused by vibration of the soft palate when paralysed. It is most often observed in persons suffering from an apoplectic stroke.

Stesichorus (c. 630-555 B.C.). Greek lyric poet. He was born at Himera in Sicily, his real name being Tisias, changed to Stesichorus (marshal of choruses) because of his occupation. His poetry, written in the Dorian dialect, was choral, and his themes were taken from the epic cycle. There is a story that he was struck blind by Helen for an attack upon her in one of his chorus songs, but recovered his sight after recantation. See Ode.

Stethoscope (Gr. *stēthos*, chest; *skopein*, to look into). Medical instrument invented by R. T. H.

Laennec. It enables the physician to hear sounds originating in the heart or lungs, or other parts of the body. Laennec's instrument was a hollow wooden tube expanded at each end. The modern form of stethoscope consists of a chest piece, from which lead two rubber tubes terminating in bone or metal ear pieces which the physician places in his ears, the chest piece being applied to the body over the organ

Stethoscope. The modern medical instrument

which is to be auscultated. See Laennec, R. T. H.

Stettin (Pol. *Szczecin*). City on the Baltic Sea. It is situated 80 m. N.E. of Berlin, and near the mouth of the Oder, and was until 1945 Germany's chief Baltic port. It lies in the part of E. Germany placed under Polish administration under the Potsdam agreement, 1945. It contains a palace of the former Pomeranian dukes, with a crypt dating from 1577, a 15th century town hall, and the churches of S. James (13th-14th century) and S. John

Stettin. Air view of the city on the Oder which was formerly the chief Baltic port of Germany.

(14th century). Most of the fortifications were pulled down in 1873.

Stettin was one of Germany's foremost industrial towns, with a huge shipyard, cement, sugar, chemical, and other industries, and a large entrepôt trade. It was a member of the Hanseatic League from 1278, and belonged to Sweden from 1648 to 1720, when it fell to Prussia. Bombed by both the R.A.F. and the Russian air force during the Second Great War, Stettin was captured from the Germans by Russian troops on April 26, 1945. Pop. 270,747.

Stettiner Haff. Lagoon of the Baltic Sea. It receives the waters of the Oder and outflows by the Swine, which separates the islands of Wollin and Usedom, the Peene, and the Dievenow.

Stettinius, EDWARD REILLY (1900-49). U.S. politician. Born in Chicago, Oct. 22, 1900, he was educated at Pomfret, Conn., and Virginia university. After working in a motor factory, he became vice-president of General Motors, 1931, and in 1934 joined the U.S. Steel corporation, rising to be chairman. In 1939 he was made chairman of the war resources board. He served as lease-lend

Edward Stettinius, American politician

tary on Cordell Hull's retirement. Stettinius was the second youngest secretary of state in U.S. history. In 1945 he was appointed American representative on the security council of the U.N., and served as chairman of the U.S. delegation in the general assembly of the U.N., 1945-46. He published *Lease-Lend: Weapon for Victory*, 1944; *Roosevelt and the Russians: the Yalta Conference*, 1949. Having returned to business, he died Oct. 31, 1949, at Greenwich, Conn.

Steuben, FRIEDRICH WILHELM AUGUSTUS, BARON VON (1730-94). German soldier of fortune. Born at Magdeburg, Nov. 15, 1730, he saw service during the Seven Years War, and in 1778 offered his sword to the American Colonies in their struggle with Britain. Appointed

Baron von Steuben, German soldier of fortune

instructor-general, he devoted himself to the task of reorganizing the raw colonial volunteers. Subsequently he received a command in the field and took a prominent part in the reduction of Yorktown in 1780. His services were rewarded with a pension and a grant of land. The latter was in New York State, near Utica, and there, calling it Steuben township, he lived until his death, Nov. 28, 1794.

Stebenville. City of Ohio, U.S.A., the co. seat of Jefferson co. It stands on the Ohio river, 44 m. W.S.W. of Pittsburg, and is served

by the Pennsylvania and other rlys. It lies in a natural gas and coal mining region, and manufactures glass, iron and steel ware, foundry and machine-shop products, paper, and flour. It assumed its present character after the sinking of the Liberty coal-shaft in its main street in 1856. Steubenville was founded in 1797, and became a city in 1851. It was built on the site of Fort Steuben, a fort erected in 1787 and named after Baron von Steuben (v.s.). Pop. 37,651.

Stevedore (Span. *estivador*, packer). Man who undertakes the loading and unloading of a ship's cargo. The master of a vessel is supposed to be a competent stevedore, but as a general rule a harbour official is appointed.

Stevenage. Market town and urban district of Herts, England. It is situated 28 miles N. of London on the Great N. Road and the main rly. from King's Cross. The town has several old and picturesque buildings, including the church of S. Nicholas, mainly early English. Alleyne's grammar school for boys was founded here in 1558. At the southern end of the town are situated Six Hills, or tumuli, standing on a narrow strip of land alongside the Great N. Road. Towards the end of Sept. an annual fair is held in the main street, when traffic is diverted. Market day Sat. Pop. 6,330.

In 1946 the minister of Town and Country Planning designated almost all the urban district, together with small parts of the rural districts of Hertford and Hitchin, as the site of a new town of 80,000 pop. Some 600 acres of the area were set aside for industrial development. There were to be six neighbourhood units, each with its own local shopping area and infant schools; and a central civic, business, and shopping area, serving all of them.

Stevenage, Hertfordshire. Parish church of S. Nicholas

Stevens, ALFRED (1818-75). British sculptor. Born at Blandford, Dorset, Jan. 28, 1818, he

studied painting in Italy, but while there turned to sculpture, and about 1841 entered Thorwaldsen's studio. He returned to England in 1843, and in 1856 began his greatest work, the Wellington monument in S. Paul's cathedral. This was left unfinished at his death in London, May 1, 1875. Stevens was the perfect modern interpreter of Renaissance art ideals.

Alfred Stevens, British sculptor

Stevens, ALFRED (1828-1906). Belgian painter. Born in Brussels, May 11, 1828, he studied under

Alfred Stevens, Belgian painter

Navez there, and Roqueplan in Paris. In 1849 he painted his first notable picture and he later frequently exhibited in the Paris Salons. He painted the elegant bourgeois life of his time, chiefly interior scenes, with furniture, costumes, etc., faithfully rendered. He died in Brussels, Aug. 24, 1906.

Stevens, JOHN (1749-1838). American inventor. He was born in New York and educated at Columbia university. Admitted to the New York bar in 1771, he later joined the revolutionary army, rising to the rank of colonel. During 1777-82 he was treasurer to the state of New Jersey. In 1784 he built a home on what was at that time the island of Hoboken, and lived there until his death. Having purchased the New York ferry, he became interested in the problems of safe and speedy navigation across the Hudson, and in 1788 he built the first multitubular boiler for marine engines and in 1802 the first steamboat with underwater propellers. He petitioned congress in 1790 to introduce a new patent law, which was the foundation of the modern patent system of the U.S. In 1832 he com-

pleted the first rly. across New Jersey. Stevens died March 6, 1838.

Stevens OR **STEPHENS, JOHN** (d. 1726). British scholar. Of supposed Irish nationality, he was a captain in the army of James II in his unsuccessful campaigns in Ireland, and, escaping attainer, made his way to London, where from about 1695 until his death, Oct. 27, 1726, he supported himself by writing, notably A Brief History of Spain, 1701, and translating from Spanish, Portuguese, Latin, and French. His translations include Bede's Ecclesiastical History, Dugdale's Monasticon Anglicanum; the comedies of Quedo, 1707; and Don Quixote, 2nd ed. 1706. He also compiled a Spanish-English and English-Spanish Dictionary, 1706.

Stevenson, HENRY WILLIAM (1874-1944). British billiards player. Born at Hull and originally a marker, he came to London as a professional in 1894, and won the professional championship seven years later, defeating Dawson by 9,000 to 8,406. Dawson regained the title in April, 1901, but in Nov. Stevenson was declared champion without a contest. He was again beaten by Dawson in 1903, but regained the championship in 1909. He was beaten by M. Inman in 1919. On June 12, 1944, Stevenson died.

Stevenson, ROBERT (1772-1850). Scottish civil engineer. He was born in Glasgow, June 8, 1772, and educated at the

Andersonian institute, Glasgow, and Edinburgh university. He learnt lighthouse engineering from his stepfather, Thomas Smith. In 1797 he was appointed engineer to the Scottish lighthouse board, a position which had been filled by his stepfather. Robert Stevenson erected a number of important lighthouses, the most famous of which was the Bell Rock. Many unsuccessful attempts had been made to erect a lighthouse on the rock, and Stevenson's success was a triumph over public opposition as well as an engineering success. Stevenson made many improvements in the methods of lighting lighthouses and lightships. He also designed many bridges, and the E. approach roads to Edinburgh, and was honoured by many British scientific institutions. He died July 12, 1850,

ROBERT LOUIS STEVENSON

L. Cope Cornford, *Author of Stevenson, in Modern English Writers*

See the articles English Literature; Essay; Novel; Short Story, etc.; also the biographies of Meredith and other contemporaries, and the entries on Stevenson's works, e.g. Catriona; Jekyll and Hyde; Treasure Island. See also Monterey

Robert Lewis Balfour Stevenson was born on Nov. 13, 1850, at 8, Howard Place, Edinburgh, the only child of Thomas Stevenson, civil engineer, whose father, Robert, was a famous lighthouse engineer, and of Margaret, daughter of James Balfour, minister of Colinton. The novelist chose in practice to alter the spelling of his second name and to drop the third.

Louis was a delicate child, and suffered intermittently from illness all his life; and the volume and finished excellence of his work are a monument to his courage and tenacity.

From the age of eight to the age of seventeen he attended various private schools; and in his vacations travelled with his father upon professional journeys in Scotland, and went abroad with him. Concerning this period of his life, Stevenson wrote in *Memories and Portraits*: "All through my boyhood and youth I was known and pointed out for the pattern of an idler; and yet I was always busy on my own private end, which was to learn to write." He entered Edinburgh University at 17, studied law, read widely in English and French, and formed many friendships. Early in 1875 he came to know William Ernest Henley, who was then a patient in the Edinburgh Old Infirmary; and thus began a friendship which, in spite of a certain estrangement towards the end, did in fact endure till death.

Early Literary Work

In 1875 Stevenson was called to the bar; but already he had achieved a place of his own in letters. The essays collected under the titles of *Familiar Studies of Men and Books* and *Virginibus Puerisque*, proved his title to an admirable craftsmanship. In 1876, after visiting Fontainebleau, where his cousin, R. A. M. Stevenson, the art-critic, was then living, and travelling with Sir Walter Simpson upon the canals of Belgium, and alone in the Cevennes, Stevenson wrote the two vivid little books, *An Inland Voyage* and *Travels with a Donkey in the Cevennes*. He also contributed to *The Academy* and *Vanity Fair*. To the weekly review, *London*, edited first by Robert Glasgow Brown and then by W. E. Henley, Stevenson contributed *The New Arabian Nights*, a brilliant fantasy. At this time, too, were published *A Lodging for the Night*, *The Sire*

de Malétroit's Door, and *Providence and the Guitar*; and Stevenson collaborated with W. E. Henley in the play *Deacon Brodie*. Before 1879 he had published *Will o' the Mill*, a delicate and a beautiful fantasy, as fine a thing as he ever did in his life.

In 1879, Stevenson, brilliant artist as he was, had not become known to the great public, so that he earned little enough by his pen. It was at this moment that a disagreement with his father left him dependent for his living upon his own exertions.

Travels in America

And here begins the second phase of his life, during which he travelled much, mingled with all sorts and conditions of men, and learned the ways of the world. Stevenson travelled to California, living at Monterey and at San Francisco, and fell very ill. Nevertheless, he wrote *The Pavilion on the Links*, drafted *Prince Otto*, and began *The Amateur Emigrant*. In 1880 he married an American, Mrs. Osbourne, née Van de Grift, and with her and her son, Samuel Lloyd Osbourne, lived at Juan Silverado, above Calistoga. The chronicle of his life here is contained in *The Silverado Squatters*. In the same year, the family difference having been composed, the Stevensons returned to Scotland, and thence went for a time to Davos, where they became acquainted with John Addington Symonds. In 1881 they were established at Pitlochry and Braemar. Stevenson wrote *Thrawn Janet* and *The Merry Men*, and during this year and the next, 1882, wrote *Treasure Island*, which made his reputation with the great public.

In 1883, while staying near Marseilles and near Hyères, he wrote *The Treasure of Franchard*, and *The Black Arrow*. To the years 1884-86 belong the delicate and beautiful *A Child's Garden of Verses*, the plays *Beau Austin*, *Admiral Guinea*, and *Robert Macaire*, written in collaboration with W. E. Henley, the second series (in collaboration with his wife) of *The New Arabian Nights*, the biography of Professor Fleeming Jenkin, and various short stories and beginnings. Then, in *The Strange Case of Dr. Jekyll and Mr. Hyde*, he achieved his second popular success. In the same year, 1886, he published *Kidnapped*.

On his father's death in May, 1887, he quitted England, never to return. With his wife, mother, and stepson he went to America. There he wrote *Ticonderoga*, contributed to *Scribner's Magazine* the essays afterwards published under the title of *Pulvis et Umbra*, wrote, with S. Lloyd Osbourne, *The Wrong Box*, a farce, and began *The Master of Ballantrae*. In 1888 the Stevensons sailed for a cruise among the Pacific Islands, in the schooner yacht *Casco*. The expedition was arranged by S. S. McClure, the American publisher, who commissioned Stevenson to write of the Islands; a task to which, strange to say, Stevenson found himself antipathetic.

During the voyage he began, in collaboration with his stepson, *The Wrecker*, a fine, spirited, humorous story. Stevenson stayed at Honolulu for about six months, and visited the leper settlement at Molokai. Thence the family sailed in the *Equator*, a trading schooner, for another six months' cruise. At Christmas, 1889, they came to Samoa, where, at Apia, Stevenson bought an estate, which he named Vailima, and settled there. Here he wrote *The Bottle Imp*. During a trip to Sydney and back, he wrote the letters for which McClure had commissioned him. Of his life at Vailima Stevenson told in the *Vailima Letters*, addressed to Sir Sidney Colvin, and published in the Edinburgh Edition of his works. At Vailima he wrote the *Footnote to History*, *Catriona*, and in collaboration with S. Lloyd Osbourne, *The Ebb-Tide*, a story of the South Seas, which in some respects is the most brilliant of his works. In 1893, during a severe attack of illness, he dictated *St. Ives*, afterwards completed by Sir Arthur Quiller-Couch.

Death at Vailima

Towards the end of 1894 he was at work on the beginning of *Weir of Hermiston*, which remains a noble fragment. On Dec. 3, while talking with his wife, he suddenly lost consciousness. A blood-vessel in his brain had broken, and he died in two hours. He was buried upon the summit of Mount Vaea.

Stevenson was a great artist. His mastery of the art of words was consummate. He owned an admirable sense of beauty, a singularly acute perception of character, a vivid faculty of humour. As an essayist, he was the maker of some among the most charming pieces in the English language. As a writer of romance, he was the greatest of his day. Whatever he touched, he touched to perfection of form. Stevenson should rather,

Stevenson, THOMAS (1818-87). Scottish engineer. Born in Edinburgh, July 22, 1818, he was the son of Robert Stevenson.

Thomas Stevenson, Scottish engineer

Educated at the high school, Edinburgh, he showed a strong bent for mathematics and was soon contributing articles to scientific journals on meteorology, etc. He joined his father in business as a lighthouse engineer, and with his brother David was responsible for the erection of several lighthouses. Making a study of lighthouse lanterns, he invented the valuable azimuthal condensing system. His principal contribution to meteorology was the development of the louvered thermometer screen which bears his name and is widely used in modified form. He died May 8, 1887. His son, R. L. Stevenson (*q.v.*), sketches his character delightfully in *Memories and Portraits*.

Stevenston. Town of Ayrshire, Scotland. It stands near the Firth of Clyde, 28 m. S.W. of Glasgow, with a rly. station. Here Nobels established a factory for making explosives. The coal mines of the vicinity are disused. Pop. approx. 12,000.

Stevinus, SIMON (1548-1620). Dutch mathematician. He was born at Bruges, but little is known of his life. He was one of the first mathematicians to deal with the properties of regular and semi-regular polyhedra, and he laid down certain of the fundamental principles of mechanics, which show that he must have been one of the leading mathematicians of his time. In 1586 he published his famous pamphlet on decimals. The place and exact date of his death are unknown. He is commemorated in Bruges by a statue in the Place Simon Stevin.

Steward (A.S. *stigo*, *sty*; *ward*, keeper). One who manages an estate. It is also used for attendants on ships and for officials at race meetings. In some churches, *e.g.* the Methodist, certain officials are known as stewards. In England the lord high steward is one of the great officers of state, and there is also a lord steward in the royal household. The surname Stewart arose from the fact that King David I of Scotland gave to a certain Walter the office of steward of Scotland. Great steward of

Scotland is one of the titles of a prince of Wales. See Bailiff; Jockey Club; Royal Household; Shop Steward; Stewart.

Stewards' Cup. English horse race. A sprint handicap for three-year-olds and upwards, it was instituted in 1840, and is run over a 6-furlong course at Goodwood (*q.v.*) on the first day of the annual meeting in July.

Stewart. Island belonging to New Zealand and separated from S. Island by Foveaux Strait. It is very mountainous, rising to 3,200 ft., is forest-clad, and is a tourist resort. Its area is 662 sq. m.

Stewart, STUART, OR STEWART. Name of a Scottish family. Scion of an ancient Breton family settled in England late in the 11th century, the first to settle in Scotland was Walter, whom David I created seneschal or steward of Scotland, granting him land in Renfrewshire. The stewardship passed in succession to James Stewart (d. 1309). From his brother John's seven sons were descended several noble Scottish families. Walter (d. 1326), 6th steward, son of James, fought at Bannockburn, and married Marjory, daughter of the Bruce. His son Robert became king of Scotland in 1371. From him descended the royal line in male succession to James V (d. 1542).

Through James's daughter, Mary Queen of Scots, the succession to the crown continued in James VI, who came to the English throne in 1603, and whose direct descendants held the crown until the death of his great-granddaughter Anne, 1714. By the Act of Settlement the succession then devolved on the house of Hanover, and the male representative of the royal house of Stuart and claimants to the throne ended in Henry, Cardinal York. See Charles Edward; James I; James Edward; Royal Family.

Stewart, ALAN BRECK. Character in R. L. Stevenson's *Kidnapped*. A Highland Jacobite, he appears early in the story, plays an active part in the hero's adventures, and reappears in the sequel, *Catriona*.

Balfour Stewart, Scottish physicist

Stewart, BALFOUR (1828-87). Scottish physicist and meteorologist. Born in Edinburgh, Nov. 1, 1828, he was educated at St. Andrews and Edinburgh

universities. In 1856 he became an observer at the Kew Observatory. In 1868 he was awarded the Rumford medal of the Royal Society for his work on radiant heat, on which he was a leading authority. Stewart became director of the Kew Observatory in 1859, and suggested the connexion between sunspots and magnetic disturbances on the earth. In 1870 he became professor of natural philosophy at Owens College, Manchester. Stewart wrote many text-books, including *Treatise on Heat*, 1866, *Elementary Physics*, 1870, *Conservation of Energy*, 1875, *Practical Physics*, 1885-87. With Professor P. G. Tait he published anonymously *The Unseen Universe*, 1875, dealing with the soul and a transcendental universe. The two authors revealed their identities a year later, and a sequel followed in 1878. Stewart died Dec. 19, 1887.

Stewart, DUGALD (1753-1828). Scottish philosopher. Born Nov. 22, 1753, he was educated at the

Dugald Stewart, Scottish philosopher

high school and university of Edinburgh, in which he became professor of mathematics in 1775, proceeding to the chair of moral philosophy in 1785. He died in Edinburgh June 11, 1828. Stewart was one of the chief representatives of the Scottish school, an upholder of the doctrine of "common sense" as the fundamental law of human belief. The existence of the Ego is suggested by the understanding; the existence of the objects of the external world is shown by the repeated perception of the same thing and the fixed and coherent order of nature.

Stewart, HENRY BENEDICT (1725-1807). Jacobite prince and cardinal. Younger son of James Edward, the Old Pretender, he was born in Rome, March 6, 1725. His father made him duke of York, and his life was passed mainly in Rome, although in 1745 he was with some French troops intended for the invasion of England. In 1747 he took orders, being at once made a cardinal, and as Cardinal York he is frequently known. A number of ecclesiastical appointments were given to him, including the bishopric of Frascati.

In 1788 he became, by the death of Charles Edward, king of Great

Britain according to legitimist ideas, and his supporters called him Henry IX. When the French invaded Italy in 1798 he was forced to leave Rome and lost his income; George III, however, made him an allowance of £4,000 a year. In 1800 he returned to Rome, where he lived until his death, July 13, 1807. He is buried in S. Peter's. Henry was the last male of the royal house of Stewart. *See* Jacobites; Stewart; *consult also* The Last of the Royal Stuarts, H. M. Vaughan, 1906; H. S., Cardinal of York, and his Times, A. Shield, 1908.

Stewarton. Market town and police burgh of Ayrshire, Scotland. It stands on Annick Water, 5 m. N. of Kilmarnock, and has a rly. station. In the town are manufactures of textiles, engineering works, and dyeworks. An agricultural district surrounds it. The name is due to a supposed connexion with the royal family of Stewart. Pop. 2,749.

Stewartry. In Scotland, former name of a district administered by a steward, a royal official having both criminal and civil jurisdiction. The term is now applied only to the stewardry of Kirkcudbright (*q.v.*).

Steyn, MARTINUS THEUNIS (1857-1916). South African statesman. Born in the Orange Free

State, Oct. 2, 1857, he was educated in Holland and England, being called to the bar at the Inner Temple in 1882. On his return to S. Africa he practised

law at Bloemfontein, becoming

state attorney in 1889, and five years later first puisne judge. President of the O.F.S. in 1896, he maintained friendship with Great Britain until 1899, when he followed the Transvaal in declaring war. On the advance of the British to Bloemfontein, Steyn took to guerrilla warfare, but was a party in the peace negotiations of 1902. Soon after the surrender at Pretoria he went to Europe. On returning to S. Africa he became a staunch supporter of the British govt. He died Nov. 28, 1916.

Steyne, MARQUIS OF. Character in Thackeray's *Vanity Fair*, suggested by either the 2nd or the 3rd marquis of Hertford. He is the wicked old nobleman whom Becky Sharp fascinates for sordid

Marquis of Steyne

From a drawing by W. M. Thackeray

S. Andrew's church, with some notable Norman work, and the grammar school, founded in 1614. Steyning was a Roman settlement and, being then on the coast, became a scaport, until the sea receded in the 14th century. It had also a famous shrine and a Benedictine religious house. From 1298 to 1832 it sent two members to parliament. The neighbouring Bramber Castle was purchased by the National Trust in 1945. Pop. 2,500. *Pron.* Stenning.

Steyr or **STEIER.** Town of Upper Austria. It stands at an alt. of over 1,000 ft. at the confluence of the Steyr and the Enns, being 85 m. W. by S. of Vienna. There are steel and iron mines, and manufactures include cutlery, paper, woollens, motor-cars, cycles, and rifles. Steyr was formerly the seat of the margraves of Styria. Morcau signed an armistice with the Austrians here, Dec. 25, 1800, after Hohenlinden. Pop. 29,110.

Stibnite or **ANTIMONITE.** A trisulphide of antimony. Grey in colour with a metallic lustre, it is found in quartz veins associated with granites, these veins often containing gold; also as replacement deposits in limestones and shale, usually with galena. Stibnite is the most important ore of antimony (*q.v.*).

Sticking (or Sticky) Bomb. An anti-tank hand-grenade that adheres to its target. Two types

were used by British infantry in the Second Great War: the self-igniting incendiary grenade, and the No. 74 anti-tank grenade. The self-igniting grenade was a short-necked half-pint glass bottle, 90

reasons, and whois thrashed by Becky's husband, Rawdon Crawley. *Pron.* Steen.

Steyning. Town of Sussex, England. It stands near the Adur, at the foot of the South Downs, 12 m. N.W. of Brighton, to which there is a rly. service. The chief

buildings are S. Andrew's church, with some notable Norman work, and the grammar school, founded in 1614. Steyning was a Roman settlement and, being then on the coast, became a scaport, until the sea receded in the 14th century. It had also a famous shrine and a Benedictine religious house. From 1298 to 1832 it sent two members to parliament. The neighbouring Bramber Castle was purchased by the National Trust in 1945. Pop. 2,500. *Pron.* Stenning.

Steyr or **STEIER.** Town of Upper Austria. It stands at an alt. of over 1,000 ft. at the confluence of the Steyr and the Enns, being 85 m. W. by S. of Vienna. There are steel and iron mines, and manufactures include cutlery, paper, woollens, motor-cars, cycles, and rifles. Steyr was formerly the seat of the margraves of Styria. Morcau signed an armistice with the Austrians here, Dec. 25, 1800, after Hohenlinden. Pop. 29,110.

Stibnite or **ANTIMONITE.** A trisulphide of antimony. Grey in colour with a metallic lustre, it is found in quartz veins associated with granites, these veins often containing gold; also as replacement deposits in limestones and shale, usually with galena. Stibnite is the most important ore of antimony (*q.v.*).

Sticking (or Sticky) Bomb. An anti-tank hand-grenade that adheres to its target. Two types

were used by British infantry in the Second Great War: the self-igniting incendiary grenade, and the No. 74 anti-tank grenade. The self-igniting grenade was a short-necked half-pint glass bottle, 90

p.c. filled with a mixture of yellow phosphorus, benzene, water, and a strip of crude rubber. The remaining space contained air. When thrown against a target, the glass broke and the oxidation of the phosphorus in the air spontaneously ignited the benzene. The rubber, which had dissolved in the mixture during storage, made the incendiary materials tacky, so that they adhered to the target.

The No. 74 anti-tank grenade was introduced into the British army in 1939, and was a spherical glass or plastic container, which held 20 oz. of nitro-glycerine jelly, and which was covered with a woollen jacket steeped in a powerful adhesive. Attached to the top was a wooden handle incorporating a lever in contact with a firing pin. When the safety pin was withdrawn and the grenade thrown, the firing pin, which detonated a 5 sec. fuse, was released. Upon striking a target, the grenade stuck to it, the container broke, and the explosive was ignited. The No. 74 anti-tank grenade was effective only against one-inch armour. *See* Grenade.

Stick Insect (*Phasmidae*). Family of orthopterous (straight-winged) insects. In them the body

closely resembles a twig, and is extremely difficult to detect when at rest among foliage. These insects, of which about 600 species are known, are common in

the tropics, where they attain a length of over 13 ins. Four or five species occur in Europe. In some species the male insect is a rarity; many generations may fail to produce one. *See* Insects; Protective Colouring colour plate.

Stickleback (*Gasterosteus*). A group of small fishes, which gain their popular name from the spines on the back. Three species occur in Great Britain, and are known as the three-spined, ten-spined, and

Stickleback. Three-spined species on guard over the nest which it has built among the weeds

fifteen-spined, the first two being fresh-water species, the third marine. Of these the first is most common. In the breeding season the male becomes resplendent with blue and red, and builds a nest in which the female deposits her eggs. The marine stickleback is about 6 ins. long. It builds a pear-shaped nest of seaweed, and has been known to keep close watch over it for three weeks.

Sticta. Genus of lichens of the family Parmeliaceae. Mainly tropical in distribution, it is leaf-like in growth, and of a leathery texture. Dyes are obtained from many species.

Stiff Neck, WRY NECK, OR TORTICOLLIS. Affection of the muscles of the neck which leads the patient to turn his head to one side, and to rotate the whole body instead of turning the head to look at an object. Several forms are recognized. The so-called rheumatic variety is due to inflammatory changes in the fibrous tissue or fascia surrounding the muscles. Chronic torticollis may be congenital, or due to cicatricial changes in the sterno-mastoid muscle which lead to its shortening. Spasmodic torticollis is a form in which the head is continually jerked or twisted to one side. It is probably due to irritation of the nerves supplying the muscles. The acute rheumatic form should be treated locally by massage and physiotherapy. Chronic torticollis generally demands a surgical operation directed towards lengthening the shortened muscle. Electrotherapy as well as local treatment of the nerves is useful in the spasmodic form.

Stigand (d. 1072). English prelate. A priest at Assundun, he became chaplain to Canute, and was a leading supporter of his widow, Emma. In 1043 he was made bishop of Elmham, in 1047 of Winchester, and in 1052 archbishop of Canterbury in place of the outlawed Robert of Jumièges. Robert, however, had not given up the see, and the pope ordered him to be restored, thereby impairing Stigand's position, though not securing his removal. Stigand did not crown William the Conqueror, nor did he consecrate many bishops; but William kept him in office until 1070, when the papal legates brought against him charges of usurpation and plurality. Stigand was put in prison and there remained until his death, which probably occurred on Feb. 22, 1072.

Stiggins. Character in Dickens's novel *The Pickwick Papers*, a par-

son in some nondescript dissenting sect, and described as a "deputy shepherd." He is represented as a canting hypocrite addicted to drink. Tony Weller's wife puts herself under his ministrations, but after her death Tony joyously ducks him in a horse-trough.

Stigma. In flowering plants, the summit of the ovary or of the style, which, if present, is a prolongation of the ovary. It is specially adapted to retain the pollen-grains which are brought to it by insects, the wind, or in self-fertilised species by the action of the stamens. This receptive portion is known as the stigma. It is generally rough, owing to a coating of short hairs or nipple-like points, which secrete a sticky liquid that holds the pollen-grains, and apparently excites them to send out the shoot-like tubes through which the male nucleus is conveyed to the ovules in the ovary. *See Flower.*

Stigmata (Gr., punctures, marks). Name for the five wounds of Our Lord, in the hands, feet, and side; also for similar marks borne by other persons. Between three and four hundred cases are on record, some of them fully attested by free-thinking physicians, of the appearance of the stigmata after prolonged meditation on the passion of Christ. One of the earliest recorded cases is that of S. Francis of Assisi. Stigmatisation is probably due to auto-suggestion, since bleeding through the skin, blisters, scars, and marks of prearranged form have been made to appear and disappear by hypnotic suggestion.

Stilbite. In mineralogy, one of the zeolite group. A hydrated silicate of calcium and aluminium, white to red in colour with a pearly lustre, it occurs in basaltic rocks and elsewhere. *See Zeolite.*

Stilboestrol. Synthetic oestrogen sex-hormone, used medicinally in a manner similar to the naturally occurring substance. A derivative of the unsaturated aromatic hydrocarbon, stilbene, it occurs as a white crystalline substance. It has given valuable results in the treatment of prostatic carcinoma in the male.

Stiletto (Ital., dim. of *stilo*, dagger). Slender, round-bladed dagger, about 6 ins. long. *See Dagger.*

Stilicho, FLAVIUS (c. 359-408). Roman soldier and statesman. A Vandal by birth, he became a notable commander and diplomatist under the emperor Theodosius I, on whose death in 395 he virtually

ruled the Western empire. Appointed guardian of the young Honorius, in 398 he became his father-in-law. Stilicho's relations with the barbarians are obscure, and probably to suit his convenience he was quite willing to intrigue with one at least of their leaders, Alaric, king of the Visigoths, though he defeated him at Pollentia in 403. He overthrew the great invading army of Rada gaisus at Faesulae (Fiesole) in 405. He had made many enemies, and as a result of their intrigues with Honorius he was murdered, Aug. 23, 408. Stilicho was the patron of the poet Claudian. *Pron. Stillyko.*

Still. Apparatus used in the distillation of alcohol. There are two chief kinds, the pot still (*q.v.*) and the patent still. *See Alcohol.*

Still-birth. Birth of a dead foetus. It is most often the result of an accident to the mother or of disease of mother or foetus. Syphilis can cause it in the human species; or the umbilical cord may strangle the infant before or during birth. *See Birth; Pregnancy.*

Still Engine. Combined internal combustion and steam engine invented by W. J. Still. The upper part of the piston acts as an oil engine, while the lower part acts as a steam engine with steam generated from the combined heat of jacket water and exhaust gases. The process of steam generation is assisted by arranging that the exhaust gases shall give up their heat to the water in a regenerator. The heat remaining in the gases after leaving the regenerator heats the water condensed from the exhaust steam leaving the cylinder, this water being used as the feed water and passed back into the jackets. Some of the heat of combustion passes through the piston and superheats the steam on the lower side, thus still further improving the economy. As only about 15 p.c. of the heat in the steam can be converted into useful work, in practice the increase in b.h.p. does not exceed 12 p.c. An auxiliary oil-burner is fitted to the boiler for use when starting up or when extra power is required. Scott-Still marine engines of 2,500 b.h.p. have been fitted to motor ships and operated satisfactorily over long periods. *See Internal Combustion Engine; Steam Engine.*

Stillingfleet, EDWARD (1635-99). An English divine. He was born at Cranborne, Dorset, April 17, 1635, and was educated at S.

John's College, Cambridge. Having been ordained, he was successively rector of Sutton, Beds, of S. Andrew's, Holborn, and canon of S. Paul's. In 1678 he was chosen dean of S. Paul's, and in 1689 bishop of Worcester. He died March 26, 1699. Stillingfleet's great learning was employed in defending his church against nonconformist and R.C. claims.

Edward Stillingfleet, English divine

A man of liberal outlook, he was one of the most noted preachers of his time. His chief writings are *Irenicum*; *Origines Sacrae*; and *A Rational Account of the Grounds of the Protestant Religion*.

Still Life. In art, the term for that class of subjects for a painting which is confined to inanimate objects in nature, such as flowers, fruit, vegetables, dead poultry or game, often grouped with appropriate manufactured articles, e.g. vases or kitchen utensils. Certain Dutch artists of the 17th century excelled in still-life painting, but it was raised to the level of high art by the French painter, J. B. S. Chardin (q.v.), who gave as much thought to the grouping of his humble subjects (fruit, bread, glasses of wine, etc.) and used them as much as a means of expressing his own poetic, impressionistic vision as Velazquez in the realm of human portraiture or Turner in that of noble landscape. But to most painters still life painting is a useful exercise rather than an end in itself.

Stilt (*Himantopus*). Wading bird of the sandpiper group, so called on account of its very long legs. There are several species, of which the black-winged stilt (*H. himantopus*) occurs as a migratory bird in Europe and is very occasionally found in Great Britain.

Stilt. Word used in several senses. In ceramic art, it is a piece of iron or hard-fired clay for keeping articles apart in the kiln. In civil engineering, it is any of the piles comprising the back of the sheet piling for a starling. The leg of a wheelbarrow, plough handle, shaft, and also a crutch are known as stilts. The word also means one of a pair of wooden poles formed with a foot rest for enabling persons to walk above ground level.

Stilton Cheese. A British veined cheese, which derives its

name from a village in Huntingdonshire on the Great North Road, whither it was brought by makers for transport by coach to London. The fame of Stilton cheese is international and is of great age in England, where already in 1736 the contemporary product was said "not to have the true Relish that the first famous Stilton Cheeses had." It was first publicly sold at the Bell Inn, Stilton, in the 18th century. The neighbouring counties of Leicester and Rutland share with Hunts in making the cheese, which is a seasonal product, depending on the richest milk supply, with occasional supplement of extra cream. It is not pressed, and is the best example of the semihard, slow-maturing, blue cheeses. The veining is produced by the penicillium mould. Good Stilton has been made in New Zealand, but with mould imported from England. The colour is white, with a crinkled but not cracked brownish rind. Gastronomes no longer support the popular theory that a good Stilton cheese is bettered by the addition of port wine.

Stilus (Lat.). Writing implement used in classical times. See under *Style*.

Stilwell, JOSEPH W. (1883-1946). American soldier. Born in Florida, he joined the army in youth, and served for two years in the Philippines before being recalled to West Point as an instructor. In 1910 he returned to the Far East, where he became an expert in Chinese language and military methods. In the First Great War he won the D.S.M. in France. Stilwell contributed much to the raising and training of the U.S. army, and the attack on Pearl Harbour led to an

Stilt. A woman stilt-walker in the hop fields at Paddock Wood, Kent

appointment as his country's military representative in China and to his selection by Chiang Kai-shek as chief of staff and commander of the Chinese armies in Burma. In early 1942 he led the heroic retreat of a remnant of his forces through the jungle and over mountains to India; and in Dec. of the same year he set out at the head of a retrained and strengthened force to build the Ledo Road (q.v.) through N. Burma to China. To his troops "Vinegar Joe," he died in San Francisco, Oct. 12, 1946, of a liver complaint contracted during the jungle retreat. Extracts from his diaries and letters were published in 1948, as *The Stilwell Papers*.

Stimson, HENRY LOUIS (b. 1867). American lawyer and politician. Born in New York, Sept. 21, 1867, he graduated at Yale in 1888 and was admitted to the bar in 1891 after studying at Harvard. As district attorney in New York, 1906-09, he successfully prosecuted the sugar trust and other powerful business concerns. Secretary of war, 1911-13, he greatly increased the efficiency of the American army. He served in France during the First Great War. Later he became special envoy to Nicaragua, 1927; governor-general of the Philippines, 1928-29; secretary of state, 1929-33, and judge of the permanent court of international justice at the Hague, 1935. He was again secretary of war during 1940-45. His policy of notifying Japan, in 1932, that the U.S. would not recognize any situation brought about by violations of the Kellogg Pact was sometimes called the Stimson doctrine. A book of memoirs appeared 1947.

Henry Stimson, American politician

Stimulant. Generally, a drug which increases the activity of an organ, e.g. gentian, which stimulates the flow of gastric juices, and strychnine, which stimulates the action of the heart. Beverages containing alcohol are called stimulants. See *Drug*.

Stinchar. River of Ayrshire, Scotland. It rises in Carrick and flows 30 m. generally S.W. past Barr to the Firth of Clyde at Ballintrae.

Sting. In insects, an adaptation of the egg-conduit (ovipositor) to serve as a weapon of defence or for incapacitating their prey. The

Joseph Stilwell, American soldier

piercing organ is connected with glands, from which a minute quantity of acid or alkaline poison flows into the puncture. These organs reach their highest development and complexity in the aculeate Hymenoptera—bees, wasps, ants, and gall-wasps. In the sand-wasps and some others that provision their cells with stung caterpillars or other insects, the effect of the poison is to paralyse the nerve-centres without

Sting. Enlarged needle of a bee's sting. *a*, barbed point; *b*, piston; *c*, base

causing death and decomposition. In the social wasps and bees the sting is used for defensive purposes or for the elimination of redundant members of the community. The sting consists of a gouge-like director, in whose concave face run two needles which push the poison before them in the director. In the scorpions the sting is a hardened and hooked point at the last segment of the narrowed hind body within which are the poison glands. The sting of the nettle consists of a hollow hair, through which poison flows when the tip is broken off.

The so-called stinging of mosquitoes, fleas, and other flies is effected by the modified mouth parts. Where fish are credited with stinging the puncture is made by a cleverly manipulated spine, and the consequent irritation or inflammation results from the introduction of slime from the skin of the fish. See Hair; Scorpion; Sting Ray.

Sting Ray. Popular name for a family of fishes (Trygonidae), in which a serrated spine is present on the whip-like tail. About 25 species of true sting rays (*Trygon*) are known, mainly restricted to the warmer seas, one species being found around the S. shores of England. Although the spine is not

connected with a poison gland, it can wound.

Stinkhorn (*Phallus impudicus*). Fungus of the family Phallaceae. The mycelium runs like a thick, white cord through leaf-mould, and bears at intervals knobs which ultimately become the size and shape of a fowl's egg. Then the top splits, and from it rapidly arises a white, spongy column, 7-8 ins. high, with a conical cap divided into open cells, which are filled with an olive-green slime containing the spores. This slime, which

Stinkhorn in its stages of development. About 1-5th natural size

attracts flies, is the principal source of the atrocious odour which gives the plant its name.

Stinkwood (*Foetidia mauritiana*). Evergreen tree of the family Lecythidaceae. It is a native of Mauritius and Madagascar. It attains a height of 30 ft., and has a tough, bitter, and astringent bark. The alternate leaves are oval, and the solitary flowers are without petals; they are succeeded by four-sided nuts. The wood has an unpleasant smell.

Stinnes, Hugo (1870-1924). German financier. Born Feb. 12, 1870, he inherited a large fortune from his father in 1897. During the First Great War he was the chief contractor for war material. After the downfall of the empire, he became a financial magnate. He bought up many newspapers, organized shipping companies,

took over engineering and mining works. His group controlled the greater part of Germany's coal, iron, and steel supply, the greatest of his concerns being the Rhine-Elbe Union. Regarded as the most powerful man in Germany, in 1921 he endeavoured to

mitigate the terms imposed upon Germany. He died April 10, 1924. The combine fell into difficulties, but his two sons reconstructed it with U.S. assistance, and under Hitler it became a main pillar of the revived German engineering and armament industry.

Stint. *Calidris minuta*, the shore bird which frequents the British coast

Stint. Genus of shore birds (*Calidris*). Three kinds of stint occur in the U.K. The little stint (*C. minuta*), no larger than a sparrow, has mottled brown and black plumage with white under parts. It is found about the E. coasts in spring and autumn, and nests in the N. of Norway. The American stint (*C. minutilla*) and Temminck's stint (*C. temminckii*) are occasional visitors to Great Britain.

Stint. An allotted portion, or an amount of work to be done within a given time. A dialect word used mainly in the N. of the U.K., it is applied in one sense to the width of coal-face each miner is expected to work; in 1947, 70,000 Yorkshire miners ceased work through a dispute at Grimethorpe colliery caused by an extension in the length of the agreed stint.

Stipend (Lat. *stipendium*, from *stips*, a small coin; *pendere*, to weigh out). Payment made periodically for services rendered. In early times it meant the payment given to soldiers; today it is the salary paid at stated intervals to a curate or other clergyman, and specifically the income from a benefice, and also that paid to a professor or judge. In Scotland it applies especially to the provision for a minister of the Established Church by free teinds (or tithes), being either money payment or payment in kind at the value of the annual rate. From this it has come to mean the salary of a minister of any church. In the R.C. Church a stipend is the fee a priest may demand for saying a special mass.

Stipendiary. Literally, one who receives a stipend. It is applied usually to the paid magistrates,

Sting Ray. The Fire Flare, occasionally found round British coasts, showing the serrated spine on its tail

who are appointed in London and certain English cities and boroughs, where the work is too heavy or intricate for the ordinary unpaid justices of the peace. Stipendiaries, who have the power of two ordinary justices, are appointed by the crown and in England and Wales must be barristers or solicitors (in London barristers only) of 7 years' standing. *See* Justice of the Peace; Magistrate.

Stipple (Dutch *stippel*, little point). Term in engraving, etching, and drawing, to denote the process of dotting or making small, short marks with a point, in order to produce detail or a local effect of light and shade. Stipple-engraving was invented in the 18th century, and, before lithography came into use, was employed as the best method of reproducing chalk drawings. Bartolozzi was its most famous exponent in England. In interior decorating the term stippling is applied to a style of painting with a rough finish.

Stipule (Lat. *stipula*, straw, stubble). Leaf-like outgrowths at the base of the leaf-stalk of some plants. There is usually a pair, and these may stand out free of the petiole, as in willow and garden geranium, or be united to it (adnate) by the greater part of their length, as in rose. In the bud they are larger than the leaf proper, which they enfold and protect during its early development. In many cases they fall off or wither soon after the leaf has expanded. *See* Leaf; Plant.

Stirling. British heavy bomber aeroplane, a product of Short Bros., Ltd. Designed before the Second Great War, the Stirling was the first four-engined bomber to reach squadron service in the R.A.F. and made its first bombing raid in Feb., 1941. With a wing span of 99 ft. 1 in., and a length of 87 ft. 3 ins., it carried a maximum bomb load of 18,000 lb., and a crew of 7, including three gunners in power-operated turrets. The standard power-plant consisted of four 1,650 h.p. Bristol Hercules radials. The Stirling was later adapted as a military transport and glider tug. *See* Aeroplane illus., p. 129.

Stirling. Royal and mun. burgh and co. town of Stirlingshire, Scotland. It stands on the Forth, 29 m. N.E. of Glasgow and 35 m. N.W. of Edinburgh, and is served by British rlys. The castle, formerly a residence of the Scottish kings, is prominent on a hill. In the precincts are parlia-

ment house, chapel royal, and palace. The castle is public property, being one of the for-

Stirling. The fortified castle, connected with most of the Scottish kings, from King's Knot

tresses maintained under the Act of Union. Other buildings include the large church of the Holy Rood, trades hall, and Cowane's Hospital, now used as the guildhall. Other features are the "auld brig" across the Forth, the statue of Bruce, and Argyre's lodging. The burgh and county buildings, infirmary, Smith Institute, and high school are modern. A rly. junction, Stirling has manufactures of leather, tartans, tweeds, agricultural implements and glass. It elects an M.P. with Falkirk and Grangemouth.

Stirling owes its importance to its position as the key to the Highlands. It was made a royal burgh about 1100, and until 1603 was in many ways the capital of the country. Near are Cambuskenneth Abbey, the burial place of James III, and Abbey Craig, crowned by the Wallace monument with a Valhalla, or hall of fame. Market day, Thurs. Pop. 28,500.

Stirling, WILLIAM ALEXANDER, EARL OF (c. 1567–1640). Scottish poet and statesman. Born at the

Earl of Stirling, Scottish poet

manor house of Menstrie, near Stirling, he studied at Glasgow and Leyden. Later he became tutor, first to Archibald, 7th earl of Argyll, and afterwards to the young king James, whom he accompanied into England in 1603. In 1621 he was rewarded with the grant of Nova Scotia and a vast hinterland, and in 1631 he received the monopoly of printing the new version of the Psalms. From 1626 onwards he was secretary of state for Scotland, and on the occasion of

the coronation of Charles I, at Holyrood Palace, was created earl of Stirling. His last years were clouded by financial trouble, he died Feb. 12, 1640. His poems include several rather laboured tragedies, Darius, 1603; Julius Caesar, 1607; some graceful sonnets, and the immense Domesday, 1614. The third part of Sidney's Arcadia (*q.v.*) in the edition of 1621 was added by him. *Consult* Memorials of the Earl of Stirling, C. Rogers, 1877.

Stirling, JAMES HUTCHISON (1820–1909).

Scottish philosophical writer. Born June 22, 1820, he was educated at Glasgow university, and for some time practised as a physician. His Secret of Hegel and Textbook to Kant are two of the most important contributions to an understanding of these writers. He also published an excellent translation of Schwegler's History of Philosophy. He died March 19, 1909. *Consult* Life, A. H. Stirling, 1912.

Stirling, MARY ANNE (1815–95). British actress, usually known as Mrs. Fanny Stirling. Born in

Fanny Stirling, British actress

London, she made her first stage appearance in 1827 under the name of Fanny Clifton. After touring the provinces with her husband, Edward Stirling, she appeared at the Adelphi

Theatre, London, in 1836 and later joined Macready at Drury Lane. In 1852 she made her greatest hit as Peg Woffington in Masks and Faces. Later she was unexcelled in such parts as Mrs. Malaprop and the Nurse in Romeo and Juliet. From 1870 she taught reciting and elocution at the Royal Academy of Music and retired from the stage in 1885. In 1894 she married Sir C. H. Gregory, but she died on Dec. 31 in the following year. *Consult* The Stage Life of Mrs. Stirling, P. Allen, 1922.

Stirling Bridge, BATTLE OF. Scottish victory over the English, Sept. 11, 1297. William Wallace had collected an army from the coast districts N. of the Tay, and awaited the English in the Stirling valley. Warrenne, earl of Surrey, with some 50,000 men, advanced to the bridge near Stirling, the only one by which the Forth could be

crossed, and that barely wide enough for two horsemen to ride abreast. Wallace, who occupied a commanding position near by, waited until half the English army was across, when he swept down and cut them to pieces, forcing those who had not yet crossed to beat a hasty retreat. See Wallace.

Stirlingshire. Midland county of Scotland. With an area of 451 sq. m., it is partly mountainous. In

Stirlingshire arms

the N.W. are outliers of the Grampians, Ben Lomond rising to 3,192 ft. In the centre are the Gargunock Hills, Campsie Fells, Fintry Hills, and Kilsyth Hills. In the E. the county is undulating and contains the carse of Falkirk and Stirling, where the soil is remarkably fertile. The chief rivers are the Forth, with its tributaries Avon and Carron, the Kelvin, and the Endrick. In the shire are parts of Lochs Lomond

Stirlingshire. Map of the Scottish county famous for its battlefields

Roman occupation. Around Stirling and Falkirk numerous battles were fought. Pop. 185,900.

HISTORICAL ASSOCIATIONS. James II and James V were born at Stirling Castle, where the latter, Mary Queen of Scots, and James VI were crowned, and Alexander I died. There, too, James II stabbed the earl of Douglas, and Lennox was killed in 1571. James III was assassinated at Beaton's Mill, a few miles from Stirling, and he and his wife, Margaret of Denmark, are buried in Cambuskenneth Abbey. George Buchanan (q.v.) was born at Killearn. Consult History of Stirlingshire, W. Nimmo, 1880.

Stirrurp (A.S. *stiráp*, *stigráp*, from *stigan*, to climb; *ráp*, rope). Loop of metal with a horizontal portion for receiving the foot of a rider, and attached by a strap to the saddle. It is used to assist a horseman in mounting, and as a support while riding (q.v.).

Stirrurp Pump. Device for the manual projection of water in extinguishing fires. It consists of a thin metal cylinder within which

slides a plunger operated by a handle at the top. At a third of the distance down the outside of the cylinder projects an inverted L-shaped piece of metal terminating in a foot-rest or stirrup. A length of hose ending in an adjustable nozzle is fitted on the opposite side of

Stirrurp Pump. A stirrup hand-pump, with dual jet and spray nozzle

the stirrup-retaining collar. To operate the pump, the free end of the cylinder is immersed in a bucket or other receptacle for water and held steady by the weight of the operator's foot on the stirrup. The stirrup pump was designed shortly before the outbreak of the Second Great War for the specific purpose of extinguishing incendiary bombs.

Stitch (A.S. *stician*, to prick). Sharp pain felt in the vicinity of the costal margin on either side of the body, usually after severe exertion. In one whose organs are sound it has no pathological significance, and passes off after rest.

Stitchwort (*Stellaria holostea*). Perennial herb of the family Caryophyllaceae, native of Europe

Stirrurp. 1. German, 12th century. 2. Arab, 15th century. 3. English soleret, or steel shoe, 15th century. 4. German, 17th century. 5. Safety stirrup used by the Young Pretender. 6. Modern pattern

and Katrine, and all Loch Arklet Agriculture is the staple industry, although the county has coal and ironstone mines. Wheat and oats are the principal crops; cattle and sheep are reared. The county is served by rly. and by the Forth and Clyde canal. Stirling is the county town; other towns are Falkirk, Grangemouth, Kilsyth, Denny, Bridge of Allan, and Bonnybridge. With Clackmannanshire the co. forms one bor. and two co. constituencies. There are many relics of

Stitchwort. Familiar wild flower growing among Dog's Mercury

and W. Asia. It has four-angled, brittle, jointed stems, which give off rigid, grass-like leaves in pairs from the joints. The pure white flowers are about three-quarters of an inch across, and the five petals are deeply cleft. One species (*S. media*) is the chickweed common in cultivated and waste places.

Stiver (Dutch *stuiver*). Obsolete Dutch silver coin, the 1-20th part of a guilder, value one penny. In the Dutch colonies it was minted in copper. The word was afterwards used of any small coin.

Stjernhielm, GEORG (1598-1672). Swedish poet and scholar. Born Aug. 7, 1598, he graduated at Greifswald, and after travelling throughout Europe became a teacher at Stockholm. He was in favour with Gustavus Adolphus and Christina, and held several appointments at Dorpat (Tartu), Trondhjem, and at Stockholm, where he died April 22, 1672. A noted etymologist, mathematician, and philosopher, he is best known as a poet. His masterpiece, *Hercules*, a didactic hexameter poem, was published in 1653.

Stoat OR **ERMINE** (*Mustela erminea*). British carnivorous mammal of the weasel tribe. It

land, but are not found in Ireland. They hunt by scent, mainly at night, and prey on rats, mice, and voles, and are serious enemies of hares and rabbits. The winter fur is in great demand. See *Ermine*.

Stobart, MABEL ANNIE ST. CLAIR (b. 1862). British organizer. She was the daughter of Sir

Mrs. St. Clair Stobart, hospital organizer

Samuel Boulton, and married (1) St. Clair Stobart; (2) J. S. Greenhalgh. After spending some years in S. Africa, she founded the women's sick and wounded convey corps, of which she commanded a detachment in the Balkan Wars of 1912-13. In the First Great War she organized hospitals (staffed by women) in France and Belgium, was taken prisoner by the Germans, and condemned to be shot as a spy. Released in 1915, she commanded a column of the 1st Serbian English field hospital in what is now Yugoslavia. Interested in spiritualism, she wrote books about it.

Stock (A.S. *stocc*, a stick). Word used in various senses. Its original meaning was that of something thrust into the ground, e.g. the trunk of a tree. From this comes its use for the original part of anything, e.g. the stock from which we are sprung. It has come to be used also for the horses, cattle, etc., kept on a farm (see *Cattle*; *Sheep*). For the financial application, see below; also *Company Law*; *Stock Exchange*.

Stock may be the goods which a tradesman has on hand at any given moment, as in the word *stocktaking*; a stiff band worn as a cravat by a man; and the foundation for soup (*q.v.*).

Stock. In finance, term used for the kind of investors' holding in a company (or in a government or municipality) which is expressed in terms of its face value. It is thus distinguished from a share (*q.v.*), or shares. These are issued and bought as definite units of varying values. Stock can be purchased to any odd amount. In other words, shares are sold by number, stock is sold in quantities of £ s. d. In the U.S.A., the term is not used in

connexion with loans or investment; there, stockholders are those who have purchased an interest in a business concern.

Stock (*Matthiola*). Herbs and shrubby plants of the family Cruciferae. They are natives of S. Europe, W. Asia, N. and S. Africa, two species being British. The popular Brompton stock is a cultivated variety of *M. incana* (British); the ten-week stock is the S.

Stock. Left, flowers of the single *Matthiola annua*. Right, flower spike of the double Brompton stock

European *M. annua*, and the night-scented stocks are *M. odoratissima* and *Hesperis tristis*. Most of the familiar varieties can be sown in the open air like annuals.

Stock. Wooden part of a firearm which supports the barrel and enables the weapon to be held. The stock of a rifle consists of the fore-end, which holds the barrel, and the butt. The barrel is attached to the fore-end by bands. The fore-end is attached to the butt by the stock bolt, the head of which is embedded deep in the butt in the stock bolt hole, in which is kept the oil bottle and the pull-through. See *Rifle*.

Stockade. Improvised defensive wall, which will afford cover to the defenders and also offer an obstacle to any attempted assault. A stockade is of no value against artillery fire, but is particularly useful for passive defence against savage tribes. The construction generally consists of a double wall of wood, bamboo, or corrugated iron, with a packing of earth or shingle between. The term is also used of stakes or piles placed across a harbour or river mouth.

Stockbridge. Market town of Hampshire, England. It stands on the Test, 19 m. by rly. N. of Southampton, and 8 W. of Winchester. It is known as an angling centre and has stables for training racehorses. There is a modern church, S. Peter's, and a town hall. Until 1832 Stockbridge sent two members to parliament. Market day. Thurs. Pop. est. 900.

Stoat. A small red-brown mammal whose coat in winter becomes yellowish white

is about 10 ins. long in body, with a tail of 4½ ins. The female is 2-3 ins. smaller than the male. In summer the fur is reddish brown above and white below, with white edges to ears and a black tip to tail. The winter coat is pure white or yellowish white, with the exception of the black tip to the tail; in this state the animal is better known as the ermine. Over most of England the seasonal change takes place only partially; but in Scotland and the N. countries generally it almost always occurs. The animal makes its home in hollow trees and in holes in banks, and here a nest of grass and leaves is formed for the young, which are born about April. Stoats are fairly common in England and Scot-

Stock Exchange (French, *bourse*; Ger., *börse*). Building in which stocks, shares, and negotiable securities are bought and sold. There are stock exchanges in London, Manchester, Birmingham, Glasgow, Cardiff, and other cities of the U.K.; in Montreal, Sydney, and Johannesburg; in New York and other American cities; and in Paris and other capitals and principal cities of W. Europe. The New York stock exchange is often referred to as Wall Street, from the situation of the building; it is one of the most important and most highly organized and mechanised markets in the world. Each stock exchange has its own rules governing membership and the conduct of business; but the general principles are similar, except that only the London stock exchange divides its members into two classes, dealers (or jobbers) and brokers. The former specialise as dealers or wholesalers in a particular range of securities, or market, buying and selling on their own account; the latter act as buying or selling agents for the public, receiving a commission for their services. They are thus the intermediaries between the public and the jobbers.

Buying and selling of securities developed about the time of the institution of the National Debt and the foundation of the Bank of England in 1694. Early in the eighteenth century stock-jobbers and stockbrokers met in Change Alley and the coffeehouses there, particularly Jonathan's and Garraway's. In 1801 the stock exchange was built of veined marble with a floor space of 25,000 feet, and a dome 100 feet high. The settling room is below. Strangers are not admitted to the floor of the house.

The London Exchange

The London stock exchange is owned by a company; for many years a board of trustees and managers, elected by the proprietors, controlled the building and managed the business side of the exchange, deriving the income from entrance fees and subscriptions of members, etc., and attending to the finance of the institution; while a committee for general purposes, elected annually, controlled the activities of members. After the Second Great War, however, it was decided to merge this dual control in one authority, the council of the stock exchange, which is elected annually. It is responsible for making, altering, and enforcing the official rules.

Members number about 4,000. Admission to membership, which requires heavy fees and sureties, is restricted to those who have served for four years as authorised or unauthorised clerks; and those who purchase a "nomination" of a deceased or retired member. Membership is for one year only, re-election being at the discretion of the council. Before re-election each member must state whether he proposes to act as a broker or as a jobber: the two functions are rigidly separated.

Making a Bargain

A person wishing to buy or to sell certain securities must employ a broker to act for him. The broker or his clerk goes to the part of the house where the jobbers who specialise in that kind of security are, and asks one of them to "make a price" in the security. The jobber then quotes two prices, say, 56s. 3d.-56s. 9d., the first being the price at which he will buy, the second the price at which he will sell. The difference between the two prices is sometimes called the "jobber's turn"; it represents his profit on each share. The broker is expected to make the best possible bargain for his client, and may ask for a narrower price. Certain transactions must be recorded (or marked); others may be. Such markings of bargains are the basis of the business done included in the daily official list, and the stock exchange prices published in some newspapers.

When the broker is satisfied with a price he sends his client a contract note, showing the exact nature and result of the transaction.

On settlement day securities have to be delivered, as well as cash paid. If they are bearer securities, the selling client merely hands them to his broker, and they are passed on to the buyer; if they are inscribed securities, the selling client (or his attorney) has to attend at the Bank of England or other office of the registrar, to be identified by his broker, and sign them away; if they are registered securities, both buyer and seller sign a deed of transfer prepared by the stockbroker. The broker of the selling client sees that the seller's share certificate is handed over and that it is cancelled by the company whose shares it represents; the broker of the buying client sees that his buyer is subsequently supplied from the company's office with a certificate for the shares bought.

During the Second Great War all transactions were made on a cash basis, and theoretically had to be completed within five days; but in 1946 the council reverted to the practice of fortnightly accounts: that is, the year is divided into fortnightly periods (accounts), and a transaction has to be completed on the last day of the account in which it occurs; the document relating to the security has to be handed over to the buying member and the cash has to be paid to the selling member. Before the war it was possible to arrange to "carry over" a transaction from one account to the next. A client who did not wish to complete his transaction could arrange for his broker to complete the bargain within the exchange and immediately to re-open it for the next account.

"Bulls" and "Bears"

This arrangement facilitated speculation by "bulls," those who think the price of a security will rise and who in consequence buy in the expectation that they will be able to sell at a profit before they are called upon to pay, and by "bears," those who think the price of a security will fall, and who therefore sell shares they have not got in the expectation that before they have to deliver the shares they will be able to buy them at a lower price. The bull who carried over his bargain had to pay the difference between his buying price and the making up price at the end of the account, plus interest, called *contango*; the bear who carried over could be in a worse plight: his broker had to find someone who was prepared to provide the stock, and the holders of stock sometimes charged heavily for the accommodation. The charge was called *backwardation*.

The council of the stock exchange, through the official rules, states in detail the method by which business shall be done, commissions that brokers shall charge and pay, securities that may be dealt in. All the securities are grouped in about 25 well-recognized divisions or markets, such as Gilt-edged, Yankees, South African Mines (the Kafir Circus), Industrials, etc. The council does not guarantee any of the securities; but has an elaborate code of rules that must be observed before dealings may begin; and an even more stringent set of regulations governing the grant of an official price quotation, i.e. the inclusion of the security among those officially quoted in the stock

exchange daily official list. Business is permitted in the house in numerous unquoted securities; but many others may not be dealt in.

The values of stock exchange securities vary from time to time, sometimes considerably. Each security represents a probability to the right to an estimated income and, in some cases, to the repayment of capital. Any news that suggests that the estimated income will be larger tends to increase the market value. Consequently some fluctuations in stock exchange values are anticipations of the effect of news. Again, if the current rate of interest falls from, say, 4 p.c. to 3 p.c., a larger capital is necessary to earn a stated income; thus, at 4 p.c. £100 yields £4 income, but at 3 p.c. £133½ is needed to secure £4.

Value of fixed income stocks tends to rise as interest rates fall, and vice versa. Securities can be regarded as commodities having specialised supply and demand conditions of their own. Also, except when a security is sold *ex-dividend*, the purchaser acquires both the security and the right to the next dividend or interest payment; the price therefore includes an allowance for this accrued dividend or interest. In addition, stock exchange prices from time to time reflect the dealers' reaction to the political situation, the policy of institutional investors, such as banks, insurance companies, etc., and the abundance or scarcity of ready money. Consult the Stock Exchange Official Rules; Stock Exchange Daily Official List; Stock Exchange Weekly Official Intelligence; The Work of Wall Street, S. S. Pratt, 1903; The Book of the Stock Exchange (3rd ed.), F. E. Armstrong, 1943; The Stock Exchange, W. T. C. King, 1947; The Stock Exchange, H. Wincott, 1947.

H. Watson

Stockholm, Sweden. 1. The town hall. 2. Kungsgatan, the busiest thoroughfare in the capital. 3. The royal palace. 4. General view from S. Catherina terrace

Stock-fish. Term applied to fish such as cod, ling, and other members of the cod family, when split, cleaned, dried, and salted for export.

Stockholm. Capital of Sweden, and its largest city. Its situation on islands and mainland at the influx of Lake Malar into the Baltic makes it one of Europe's most imposing cities. Stockholm is connected by rly. with Malmö and Gothenburg, and also with Oslo and Trondjhem.

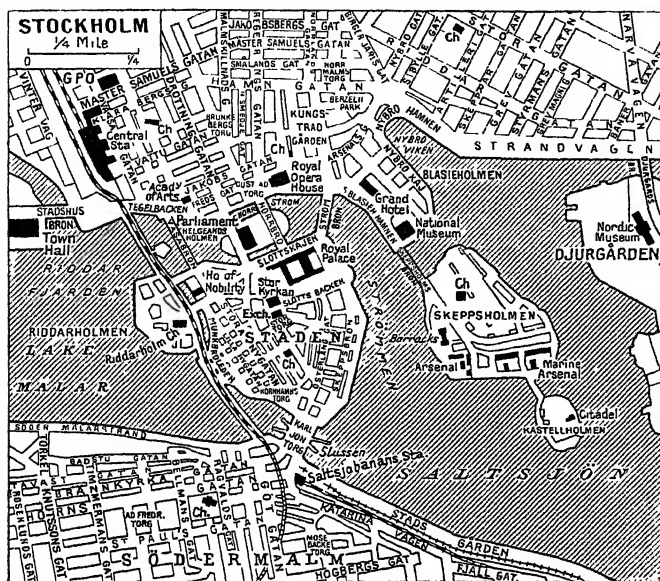

Stockholm arms

The city is composed of several districts: (1) the "old town," on Stadholmen and Helgeandsholmen, containing the royal palace and most of the government offices; (2) Norrmalm, to the N., the commercial and financial centre, where are also the chief newspaper offices; (3) Östermalm, mainly residential and military; (4) Kungsholmen, to the W., headquarters of municipal administration; (5) Södermalm to the S.,

industrial and residential; and (6) the newer garden suburbs farther W. and S., including Bromma and Spånga, incorporated into the city at the beginning of 1949. At Bromma is situated the Stockholm airport.

The pop. at the end of 1947 was 703,000 approx. More than one-third were living in the garden suburbs, and this tendency has noticeably increased, necessitating developments in external communication. An underground rly. was under construction in 1948.

Stockholm, as befits the most important trading town in Sweden, has a magnificent harbour. Main imports are coal and coke, oils and rubber, metals, grain, chemicals, and groceries; main exports are ores and minerals, metal products, pulp, paper, and cardboard, and machinery and tools. The city's own industries include the manufacture of metal goods and machinery, including electrical and telephone equipment, paper, textiles and garments, and provisions. There are important printing and industrial chemical works.

Stockholm. Plan of the Swedish capital, showing the old town on Lake Malar and its suburbs on each side of the harbour

Chief buildings include the royal palace, built 1697-1754, in Renaissance style; the Gothic (13th cent.) Riddarsholm church, burial place of Sweden's kings; the Riddarhuset (house of nobility) in Dutch classical style, containing a collection of armorial bearings; the houses of parliament (1898-1905); the bank of Sweden (1894-1906); in Normalm, the Royal Opera House, the national museum, the concert hall (1926), and the city library, an early example of "functional" architecture, built 1924-27; in Östermalm, the national library (700,000 books and 12,000 MSS.), the technical college, and the stadium; and in Kungsholmen, the town hall, completed in 1923, an internationally famous example of modern architecture. The "south town hall," in Södermalm, was erected in the 17th century. The island of Kastellholmen, S.E. of Normalm, is a naval station. The royal deer park, S.E. of Östermalm, is a popular place of resort, in which is situated the Nordic museum. Close by is an open-air museum and zoo.

According to tradition, Stockholm was founded by Birger Jarl in 1255. The oldest charter extant is dated 1436. In 1520 the town surrendered to Christian II of Denmark, who ordered mass executions of the nobility (Stockholm's "blood bath"). A peaceful period began with the entry of Gustavus Vasa in 1523. The 17th

century saw the govt. of the kingdom centralised in Stockholm, which then first became the official capital. The abolition of the guild system in 1846, and the consequent freedom for inhabitants to choose their own means of livelihood, led to a remarkable increase in the pop., which grew from 93,000 in 1850 to 301,000 by 1900.

Stockholm, TREATY OF. Agreement concluded between Great Britain and Sweden, Nov. 20, 1719. By it George I obtained for Hanover the duchies of Bremen and Verden, and Stettin for his ally, the king of Prussia. There were also treaties of Stockholm between Sweden and Russia, March 24, 1724; Sweden and Great Britain, March 3, 1813; Sweden, France, and Great Britain, Nov. 21, 1855.

Stockings. Close-fitting knitted coverings for the leg and foot.

Until the 16th cent. stockings were of cloth. Queen Elizabeth was presented by Mistress Montague with "a pair of black knit silk stockings which pleased her so well that she would never wear any cloth hose afterwards." In the 20th cent. good quality stockings, whether of silk, rayon, nylon,

cotton, or wool, are "fashioned," i.e. shaped so that they fit closely over the calf. This process requires special machinery and skilled operatives, and during and for some time after the Second Great War shortage of skilled workers in the U.K. led to the production in that country for home consumption of many more unfashioned stockings than in normal pre-war years. Clocks, formerly often seen on stockings and socks, seem to have been a survival of the days of cloth stockings, for the word signifies a gore or seam, embroidery being used to cover the join. See Hose; Hosiery.

Stockmar, CHRISTIAN FRIEDRICH, BARON VON (1787-1863). German adviser of Queen Victoria.

Born at Coburg, Aug. 22, 1787, of a noble family of Swedish origin, he studied medicine, and became physician and adviser to Prince Leopold of Saxe-Coburg.

He promoted the candidature of Leopold as king of the Belgians, and was recommended by that prince to his niece Victoria, on her coming of age, as political tutor. During the first months of the queen's reign Stockmar remained at the English court in an unofficial capacity, and later passed a good deal of time in England as a personal friend of the sovereign and the prince consort. He died at Coburg, July 9, 1863.

Stockport. County borough of Cheshire and Lancashire, England. Standing where the Goyt and Tame unite to form the Mersey, it is 6 m. S.E. of Manchester and is a rly. centre, with stations at Edgeley and Tiviot Dale. Buses and trams connect it with Manchester and

Baron von Stockmar, German statesman

Stockport, Cheshire and Lancashire. The town hall

other places. The buildings include S. Mary's church, with a 13th century chancel, the modern town hall, and the grammar school founded in 1487. There is a museum in Vernon Park. The large Sunday school is a feature of the town. Stockport is built on the sides of a

Stockport arms

narrow ravine, which is crossed by several bridges. Its industries are engineering, those connected with the cotton manufacture, and making felt hats. Heaton Norris and Reddish are the parts in Lancashire, being on the N. side of the Tame. Originally a Roman station, Stockport was made a borough in the 13th century. Since 1832 it has sent two members to parliament. Market days, Fri. and Sat. Pop. est. 142,540.

Stock Prize. French literary award, formerly called the Femina-Vie Heureuse prize. Awarded annually and worth £40, it was presented by the French magazines Femina and Vie Heureuse for what the selection committee considered the best work of imagination by one of the younger British authors, or one deemed not to have received adequate recognition. A reciprocal English prize for French authors, later called the Heinemann prize, was combined with the other in 1935 as the Stock-Heinemann prize. Awards were suspended for the duration of the Second Great War. The prize was first won in 1919 by Cicely Hamilton's William an Englishman. Other successful authors were Rose Macaulay, Gordon Bottomley, E. M. Forster, Mary Webb, Virginia Woolf, H. M. Tomlinson, Charles Morgan, Richard Hughes, Stella Benson, Richard Church, and Robert Graves.

Stock Raising. On this industry, see entries on the various classes of livestock, e.g. Cattle; Sheep, etc.

Stocks. Wooden structure for confining the legs, formerly employed as a mode of punishment. Stocks consisted of two pieces of wood, fitting edge to edge, with semicircles cut out of the contiguous edges just large enough to hold a man's ankle and keep it securely when the boards were locked together. The stocks were frequently on the village green, and seated on a bench or on the ground, with his ankles and sometimes his wrists confined, the offender was exposed to the jeers of all who passed by. Almost universally

used for minor offences, stocks were first employed in England in Saxon times, and were later set up in every village. This method of punishment fell into disuse in the early 19th century. There are still stocks, with whipping posts attached, in many English villages, though the last in London was removed from S. Clement Danes, Strand, in 1826. See Pillory.

Stocksbridge. Urban dist. of Yorkshire (W.R.), England. It is 8 m. from Sheffield, and is a coal-mining centre, having also iron and steel works. Pop. est. 9,000.

Stockton. City of California, U.S.A., the co. seat of San Joaquin co. It stands on a branch of the San Joaquin river, 80 m. E.N.E. of San Francisco, and is served by the Atchison, Topeka, and Santa Fé and other rlys. It trades in grain, fruit, and cattle, and manufactures mining and farming implements, foundry, machine-shop, and lumber products, leather, flour, and soap. These products of the rich San Joaquin valley are shipped from a water-front 18 m. long. Settled in 1847, Stockton became a city in 1850. Pop. 54,714.

Stockton-on-Tees. Mun. borough and seaport of Durham, England. It stands on the Tees, 4 m. from its estuary and 4 m. from Middlesbrough. It is served by rly. The chief buildings are the town hall, exchange, free library, and other public buildings. Ropner Park is one of several recreation grounds. The chief industries are blast furnaces, ironworks, foundries, machine shops, and glass works. There is some shipping,

Stockton-on-Tees arms

coal being exported. Thornaby-on-Tees is across the Tees in Yorkshire. Stockton was made a borough in the 14th century and had a castle which was taken by the parliamentarians in 1644. Since 1867 it has sent one member to parliament. From here to Darlington ran the first passenger railway line in England, opened Sept. 27, 1825. A mile to the N. is Norton, where is a fine old church, S. Mary's. Market day, Wed. Pop. 67,697.

Stockton-on-Tees, Durham. Town Hall, and Doric column erected as a market cross

Stockwell. Dist. of S.W. London. In the bor. of Lambeth, it lies between Clapham, S., and N. Brixton, N. Here was the Stockwell Orphanage, founded in 1867 by C. H. Spurgeon, which maintained some 500 children. At the outbreak of the Second Great War it was closed, the children being sent to Reigate and Birkington; they were not brought back to Stockwell after the war. In Landon Road is the South-Western Fever Hospital, established in 1877. Stockwell station is on the Morden-Edgware underground rly.

Stock Yard. Open, covered, or partly covered space in which cattle are kept when not on the land. See Farm.

Stoddart, ANDREW ERNEST (1864-1915). British sportsman. He was born at S. Shields, March 11, 1864, and in 1885 joined the Hampstead C.C., making his first appearance for Middlesex. He went to Australia with the 1887-88 and 1891-92 teams, and in 1894-95 and 1897-98,

A. E. Stoddart, British sportsman

Stocks formerly used for the punishment of minor offenders, still existing in a few English villages

when he was captain. A hard-hitting batsman, and a fair change bowler, he was for years the mainstay of the Middlesex team. Playing for Hampstead against the Stoics on Aug. 4, 1886, he scored 485 out of 814. He was also one of the finest of Rugby Union players, taking part in ten international matches. He died April 3, 1915.

Stoicism (Gr. *stoa*, porch). Greek philosophical system, a development of Cynicism. Founded at Athens by Zeno of Citium in Cyprus, about 300 B.C., it divided philosophy into logic, physics, and ethics. Logic furnishes the means of acquiring true knowledge. All knowledge comes from sensual perceptions, which the understanding combines into general notions, but only those perceptions and notions are true which irresistibly carry conviction. Physics teaches the laws of the universe. Only bodies (including feelings and attributes), things which act and feel, are real. There are two principles of things: passive matter and active God, the soul and former of the universe. God is a living fire (also called aether), the universal intelligence. Man's soul is a fiery vapour, partly divine, but perishable.

Ethics provides rules for practical life. The laws of nature being the laws of God, virtue consists in living according to nature in rational action. Pleasure is not an end, but rather an evil than a good. Virtue alone brings happiness; external possessions are indifferent. There is no mean between virtue and vice; a man is wholly virtuous or wholly vicious. The wise man is the pattern of virtue, the ideal of all classes of mankind, free from all faults, weaknesses, and passions, free from external restrictions, happy in all conditions. The Stoics thought suicide permissible as an aid to independence. Many distinguished Romans were followers of Stoicism—Cato of Utica, to some extent Cicero, the poet Lucan, Seneca, the emperor Marcus Aurelius. The modern definition of stoicism as indifference to pleasure and (especially) pain, accentuates the idea that the wise man is independent of all bodily conditions and external relations. See Ethics; Philosophy.

Stoke. English place-name. It is generally regarded as meaning a fenced place, being thus connected with the word stockade. Stoke-on-Trent is entered thus. Stoke in Notts, 4 m. E. of Newark, was the scene of the battle wherein Henry VII defeated the forces of

Stoke Newington. Parish church of S. Mary, designed by Sir Gilbert Scott, seen from Clissold Park

Lambert Simnel (*v.i.*). Stoke d'Abernion, Surrey, has in its church the oldest brass in England, that of Sir John d'Abernion (see Brasses). See Stoke Poges.

Stoke, BATTLE OF. Fought between Henry VII and a force of foreigners and rebels raised in the interest of Lambert Simnel, June 16, 1487. The force, collected mainly in Burgundy by Henry's enemies, landed in Dublin in May. Its backbone was composed of 2,000 German mercenaries. A number of Irishmen joined them, and in June the army landed in Lancashire. After manoeuvring for position, they faced Henry's forces at Stoke in Notts. The battle between the Germans and Henry's own division of men-at-arms was fierce. Losses on both sides were heavy, but at last the rebels broke and fled.

Stoke Newington. Met. bor. of the co. of London. It includes the old parish of the same name, to which in 1900 was joined the urban dist. of S. Hornsey, and has Islington W. and Hackney E. British Railways, buses, and trolley buses connect it with the City of

Stoke Newington arms

London. The 16th century church of S. Mary, which has interesting monuments, was superseded as parish church by the spacious Early Decorated structure of Sir Gilbert Scott, consecrated in 1858. Both churches were damaged in air raids in 1940. Clissold Park, through

which winds the New River, was acquired for the public for £96,000 and opened 1889. To the N. of the park are works of the M.W.B. and New River reservoirs; to the E. is Abney Park cemetery (*q.v.*), occupying the site and grounds of Abney House, built in 1669. There are a town hall, assembly hall, and public library. The district has included among its residents Gen. Fleetwood, Isaac Watts, Isaac D'Israeli, Poe, John Howard, the philanthropist, T. Day, author of Sandford and Merton, Mrs. Barbauld, and Defoe, after whom a street is named. It joins with Hackney N. to elect an M.P. Pop. 46,700.

Stoke-on-Trent. Full name of the city and co. bor. of Staffs, England, which in 1910 was

Stoke-on-Trent arms

formed by amalgamation of the boroughs of Burslem, Hanley, Longton, and Stoke-upon-Trent, and the urban dists. of Fenton and Tunstall. This city is the headquarters of the pottery industry of Great Britain, and lies about 150 m. N.W. of London by rly. Three members are elected to parliament by a pop. est at 274,000. See separate articles on each former borough; also Five Towns.

Stoke Poges. Village of Bucks, England. It is situated 20 m. W. of London, and 2 m. N. of Slough rly. station. The chief building is the church of S. Giles, parts of which are Norman and Early English. This has memorials of the family of Moleyns, and its churchyard was the scene of Gray's *Elegy*, also the burial place of the poet. In 1921 land near the churchyard was vested in the National Trust. See Gray, T.

Stoke Poges, Bucks. The parish church of S. Giles, and the churchyard which inspired Gray's *Elegy*

Stoker. Attendant of a hand-fired solid-fuel-burning furnace who feeds fuel into the fire, periodically freeing the grate of ash and clinker. Men so employed are known as stokers in warships, and as firemen in the merchant navy and in land installations. The increasing use of pulverised coal and oil fuel for steam raising, and of internal combustion engines of the diesel type for ship propulsion, have greatly reduced the heavy labour of the manually-operated furnace. In modern installations fuel and air supplies may be varied to suit fluctuations of load by valve manipulation at a central control panel, incorporating dial indicators that show, and often record, the condition existing in every part of the plant.

The term is also applied to mechanical devices supplying solid fuel to furnaces. Three principles are employed in mechanical firing; overfeeding, coking, and underfeeding. Overfeed stokers throw fuel over the firebed by means of moving shovels or rotary distributors, and normally incorporate a fuel hopper from which graded coal falls to the distributing mechanism. These stokers imitate one or other of two systems of hand firing, the spreading method in which coal is spread equally over the firebed, or side-firing in which fuel is thrown over the right and left sides of the fire alternately, so that one half is always in good condition, and able to burn the volatiles given off from the coal last added to the other side.

Coking stokers imitate another method of hand firing, that of distilling volatiles from fresh fuel on the front firebars, and burning these over the incandescent bed before burning the residual coke. Underfeed stokers have no parallel in hand firing. Graded coal passes from a bunker or hopper along a horizontal duct, containing a slowly-turning helically-finned shaft, to the bottom of a basket-like retort in the middle of the combustion chamber. As the fuel is forced upwards to the fire, the volatiles are released just below the level at which air enters the grate, and burn in the upper incandescent layer of previously coked coal. The ash, largely fused to clinker, is pushed on to a firebrick bed surrounding the retort.

J. W. Cowan, A.M.I.E.H.V.E.

Stokes, SIR GEORGE GABRIEL (1819-1903). British mathematician and physicist. Born at Skreen, co. Sligo, Aug. 13, 1819, and educated at Bristol and Pem-

Sir George Stokes, British mathematician

Rumford medal of the Royal Society, 1851, for his study of fluorescence, became secretary of the society in 1854, and president, 1885-90. He received the Copley medal of the society, 1893, and was honoured during his lifetime by every important scientific body. During 1887-91 he represented his university in parliament. He died at Cambridge, Feb. 1, 1903.

Stokes was one of the most brilliant mathematicians of the 19th century, and a great personal friend of Lord Kelvin. To him is due the modern theory of motion of viscous fluids, on which he published papers in 1845 and 1850, while in optics his theory of diffraction opened up hitherto unexplored fields of research. He was the practical founder of the science of geodesy, discoverer of the nature of fluorescence, and an original and brilliant investigator. His works were published in five vols., 1880-1905, as *Mathematical and Physical Papers*. See Stokes's Law, Stokes's Theorem.

Stokes, WHITLEY (1830-1909). Celtic scholar. Born in Dublin, and educated at the university, where his father was professor of physics, during 1862-82 he lived in India, where he held several important posts, and drafted the codes of civil and criminal procedure. His reputation, however, rests upon his numerous works connected with the Celtic languages—Irish, Breton, and Cornish. He died in London, April 13, 1909.

Stokesay. Village of Shropshire, England. The village, 6½ m. N.W. of Ludlow, has a church dating from the 17th century, and is famous for its castle. It is a fine example of a fortified residence of the 13th century, and is surrounded by a moat. The great banqueting hall and solar are notable. The rly. station for the village is known as Craven Arms and Stokesay. Pop. 1,100.

broke College, Cambridge, he was senior wrangler and first Smith's prize-man, and was appointed Lucasian professor of mathematics at Cambridge, 1849. He was awarded the

Stokes Gun. Type of trench mortar. Designed by Sir Wilfred Stokes (1860-1917) in 1915, this mortar was largely used in trench warfare in the First Great War, with deadly effect. It consisted of a steel barrel terminating in a breech fitted with a fixed striker. The upper part of the barrel had a sliding pin across its diam.; this could be withdrawn by pulling a lanyard. The projectile, a cylindrical case containing a charge of high explosive and an impact fuse, had at its base a 12-bore cartridge fitted with a propellant charge. When the projectile was placed in the barrel it rested on the sliding pin until the lanyard was pulled, when it fell to the breech. The cartridge in the base touched the striker, to ignite the propellant charge and blow the projectile out of the barrel. The mortar had a rate of fire of 40 r.p.m. and an effective range of 300 yds. The ordinary infantry Stokes gun fired a 20-lb. projectile, but a howitzer type discharged a 150-lb. bomb. All were already replaced before the Second Great War by the more accurate 2-in. to 6-in. mortars. See Mortar.

Stokesley. Market town of Yorkshire (N.R.), England. It stands on the Leven, in Cleveland, 16 m. S.E. of Stockton-on-Tees, with a rly. station. The old church of S. Peter was rebuilt in the 18th century, and there are a town hall and an endowed school. Around are ironstone mines. Market day, Mon. Pop. 1,700.

Stokes's Law. Principle of physics formulated by G. G. Stokes (v.s.) which relates to the resistance experienced by a body when moving through a fluid medium at moderate velocities. If the body is spherical and of radius r , if v is its instantaneous velocity and η the viscosity of the medium, then the resistive force experienced is given by $F = 6\pi\eta rv$.

Stokes's Theorem. In mathematical physics, statement that

Stokesay, Shropshire. The old gatehouse of the castle, a superb example of the timbered architecture characteristic of this part of England

the surface integral of the curl of a vector field **A** taken over any surface is equal to the line integral of **A** taken around the periphery of the surface.

Stoke-upon-Trent. Part of the city of Stoke-on-Trent, Staffs, England. In the centre of the Potteries, it is 146 m. N.W. of London, and is well served by rly. and on the Grand Union Canal. Stoke owes its growth entirely to the pottery industry started by Josiah Wedgwood. Before the introduction of this in the 18th century it was a country village. In 1832 it began to send members to parliament—until 1950 it had one of the city's three; in 1874 it received a bor. charter, and in 1910 became part of the co. bor., later city, of Stoke-on-Trent. Principal buildings are the town hall, partly dating from 1834; the church of S. Peter ad Vincula; N. Staffs royal infirmary; N. Staffs technical college, opened 1914; Minton art school (1856), commemorating a celebrated potter; assembly hall; and public library.

Stokowski, LEOPOLD ANTONI STANISLAW BOLESŁAWOWICZ (b. 1887). American conductor. Born

Leopold Stokowski, American conductor

in London of Polish parents, he received training at the R.C.M. before going to America. He possessed all-round musical ability combined with a flair for orchestral management, and at 22 was chosen conductor of the Cincinnati orchestra. From 1913 to 1936 he was in charge of the Philadelphia orchestra. In 1915 he became an American citizen. With Deanna Durbin he appeared in the film *A Hundred Men and a Girl*, 1937, and with Walt Disney he made the cinema classic *Fantasia* (q.v.), 1941, conducting his own transcription of Bach's toccata and fugue in D minor.

Stolberg, CHRISTIAN, COUNT VON (1748–1821). German poet. Born at Hamburg, Oct. 15, 1748, and educated at Göttingen, he became one of the patriotic literary group known as the Hainbund (Sylvan League). In the public service of Holstein,

Count Stolberg, German poet

1777–1800, he died Jan. 18, 1821. Besides writing poems and dramas, he made translations from the Greek, his translations of Sophocles, 1787, becoming a standard work.

A brother, Friedrich Leopold Stolberg (1750–1819), also a poet of the Göttingen school, was born at Bramstedt, Holstein, Nov. 7, 1750. During 1777–1800 he filled various diplomatic positions, and he died Dec. 5, 1819. He wrote poems on freedom, made translations from the Greek, and wrote a novel, *Die Insel* (The Island), 1788, and a *Life of Alfred the Great*, 1815.

Stole (Lat. *stola*, long robe). Ecclesiastical garment. Originating in the Roman *lorum*, a long scarf worn as a sign of office by magistrates and officials, it is from 3 ins. to 4 ins. wide and, when passed over the neck, each end reaches to about the knee. The ends are often ornamented and in the R.C. ritual the colour varies according to the season.

Stole used in the Anglican Church

Stolen Goods. By English law, the property in stolen goods remains in the lawful owner; and he may recover them from whomsoever has them, however much the possessor may have paid for them. To this rule there is a common law exception. When the goods have been sold in market overt (q.v.) the property passes to the buyer, provided, however, that, if the true owner of the goods prosecutes the thief to conviction, the goods revert in the true owner.

Stoll, SIR OSWALD (1866–1942). British theatre proprietor. Born in Melbourne, Australia, Jan. 20, 1866, he was educated at Liverpool and assisted his mother in the management of the Parthenon music hall there. He became a variety agent, and in the 1890s opened the Empire, Swansea, and Empire, Newport, where he introduced two houses a night. In 1900 Stoll's interests were merged with the Moss and Thornton management, the combination known as Moss Empires Ltd. being launched,

the London Hippodrome opened, and the Coliseum built. He left the organization to take over management of the Coliseum.

later obtaining control of the Alhambra and the London Opera House, which was converted into a cinema (see Stoll Theatre). He became chairman of

Sir Oswald Stoll, British theatre proprietor

two film companies. During the First Great War he initiated a scheme to provide and maintain houses for disabled ex-officers and their families, and he was knighted in 1919. He died Jan. 10, 1942.

Stoll Theatre. London playhouse in Kingsway, W.C.2. Designed by Bertie Crewe and erected by Oscar Hammerstein for the production of opera, it was known as the London Opera House and opened Nov. 13, 1911, the first production being *Quo Vadis*? Hammerstein's ambition to make his theatre a parallel to Covent Garden proved unsuccessful, and the building was closed in 1913, to be reopened next year as a variety theatre. After the First Great War it was converted by Sir Oswald Stoll into a cinema and renamed the Stoll Picture Theatre. During the Second Great War it staged variety and concerts, and ice entertainments were a later novelty.

Stolp (Pol. *Slupsk*). Town of E. Europe, in that part of Germany placed under Polish rule by the Potsdam agreement, 1945. It stands on the Stolpe, 85 m. W. of Danzig. The chief buildings are the churches of S. Mary (14th century), with a lofty tower and a fine carved pulpit, and S. John (15th century); the castle, a 16th century building; and the modern town hall. The manufactures of Stolp included cloth, paper, machinery, and leather. Its port is Stolpmünde (Pol. *Ustka*), at the mouth of the Stolpe, 10 m. N. of the town. Stolp was in the Middle Ages a member of the Hanseatic League and a fortified town. It was in the duchy of Pomerania, passing to Prussia in 1637. Its capture by the Russians March 9, 1945, cut off the Germans in the Danzig area. Pop. (1935) 45,507.

Stomach (Gr. *stomachos*, from *stoma*, mouth). In man, the receptacle for food after it has been swallowed. It is the most dilated part of the alimentary canal. The stomach is roughly conical in shape,

the base or fundus being on the left side of the body. The upper border is concave and is called the lesser curvature; the lower border is convex and is known as the greater curvature. The oesophagus or gullet opens into the upper part of the fundus by means of the cardiac orifice. The right extremity of the stomach is known as the pylorus and passes into the duodenum, the beginning of the small intestine.

The stomach is about 10 to 12 ins. long, and 4 to 5 ins. in diameter in the widest part. It lies beneath the diaphragm, or broad horizontal muscle, and is in close relation with the liver and pancreas. It is supplied by the pneumogastric nerves and the sympathetic nerve system. Externally the stomach is covered almost completely by the peritoneum. Beneath this are three muscular layers, and internally the organ is lined by mucous membrane, which contains three varieties of secreting glands.

The mixed secretion forms the gastric juice, which plays an important part in digestion. It is antiseptic, owing to the presence of hydrochloric acid; it converts sucrose into glucose and fructose; splits fats into simpler bodies; curdles milk; and converts the proteins of food into peptones, which are soluble. The digestion of food in the stomach is assisted by movements in the stomach, which mix the different constituents together and gradually pass them on into the intestines. The average time taken for the complete emptying of the stomach after a meal is about three hours.

Ulceration of the stomach is a disorder met with in both sexes. The cause is unknown, but the complaint is specially associated with arteriosclerosis, chronic indigestion, and worry. The ulcer is usually on the pyloric end. Most cases recover with appropriate dieting and medicinal measures. In severe cases an operation for excision of the ulcer may be necessary. Perforation of the ulcer may cause death from peritonitis, or a large blood-vessel may be eroded and death occur from haemorrhage. Cancer of the stomach most usually affects the pyloric end, and is more frequent in males than in females. See Anatomy; Dyspepsia; Gastritis; Man.

Stomach Pump. Instrument for removing the contents of the stomach in cases of poisoning. It is now rarely used, having been superseded by syphonage by means of a simple indiarubber tube terminating in a glass funnel.

Stomach. Diagram of the human organ, showing its blood and lymph supply and its relation to the intestines

Stomata (Gr., mouths). In botany, term applied to minute openings in the epidermis of leaves through which air is admitted to the cellular tissues (see Mesophyll), and excess of water evaporated. The slit-like opening is bounded by two kidney-shaped guard-cells with their concavities facing. When these guard-cells are turgid with moisture the stoma is open; when there has been excessive transpiration, the guard-cells become more flaccid and the opening is closed. **Stomata**, though found on both surfaces of the leaf, are far more abundant on the lower side. See Potato.

Stone. Measure of weight. The standard British stone of 14 lb. is known as the imperial stone. Other stones in use vary in weight according to the substances weighed, and often according to the locality. A butcher's and fishmonger's stone is 8 lb., that for cheese 16 lb., for hemp 32 lb., and for wool 24 lb. See Weights and Measures.

Stone. In geology, small fragment of rock. The name is applied particularly to small weather- or water-worn fragments, and also to those portions of rocks which are shaped and dressed for building, i.e. building stones. Stones for particular uses are generally designated by some qualifying word, e.g. hearthstone. Precious stones are those minerals, as diamonds, rubies, etc., distinguished by their beauty, colour, and rarity. The word is also applied to the hard kernels of certain fruits, e.g. cherry stones. See Building Stones; Geology; Precious Stones; Quarrying; Rock.

Stone. In pathology, a hard concretion formed in the kidney or bladder and much less frequently, in other organs. Gout is probably the most frequent cause, but stones may result from any faulty metabolism of salts and minerals. See Bladder; Calculus; Kidney.

Stone. Urban dist., and market town of Staffordshire, England. It stands on the Trent, 7 m. N. of Stafford, and has a rly. station at a main line junction. The chief buildings are the church of S. Michael, the successor of the abbey church, S. Dominic's priory, a town hall, market hall, and a grammar school of 1558. The industries include brewing, glass making, ceramics, and making footwear. Stafford and Stone is the name of a co. constituency. Market day, Tues. Pop. est. 8,500.

Stone. River of Tennessee, U.S.A. It flows N.W. to join the Cumberland river, about 5 m. above Nashville.

The battle of Stone River was a Federal victory in the American Civil War, also known as the battle of Murfreesboro. It was fought Dec. 31, 1862-Jan. 2, 1863. The Tennessee army, numbering 38,000 under Bragg, after their retreat from Kentucky, had taken up position at Murfreesboro. After preliminary skirmishing Rosecrans, the Federal general, at the head of 47,000 men, advanced against Murfreesboro, Dec. 29, and two days later the Confederates attacked the Federal right. At first the Southerners were successful, but when night fell they had not only been held along the line but repulsed at several points. On Jan. 2 Bragg renewed the attack, but the Federals advanced across the river, and the next day entered Murfreesboro. The Federals lost 13,000 men and the Confederates 11,500 men.

Stone, CHRISTOPHER REYNOLDS (b. 1882). British journalist and broadcaster. Born at Eton, Sept. 19, 1882, and educated there and at Christ Church, Oxford, he became London editor of the Gramophone, probably the first magazine to treat recorded music seriously. This was founded by Stone's brother-in-law Compton Mackenzie. Stone made his name as a broadcaster in the early days of the B.B.C. with his series of programmes of gramophone records interspersed with genial comments, a type of programme which he may be said to have invented and in which he remained for many years without a rival. His easy manner at the microphone recommended him for wide use as a compère of many other types of light radio programmes. A book of broadcast talks, *Christopher Stone Speaking*, appeared in 1933.

Stone, HARLAN FISKE (1872-1946). American judge. Born at Chesterfield, N.H., Oct. 11, 1872

he was educated at Amherst College and Columbia university. He became a lawyer in New York, but returning to Columbia was appointed professor of law, 1902, and dean of the law school, 1910. He went back to private practice, 1923. The following year he was appointed attorney-general, in 1925 associate justice of the supreme court, and in 1941, chief justice, succeeding Hughes. He died at Washington, April 22, 1946.

Stone, MARCUS (1840-1921). British artist. Born in London, July 4, 1840, a son of Frank Stone,

Marcus Stone,
British artist

artist and close friend of Charles Dickens, he studied under his father, and after considerable work as an illustrator, specialised in sentimental or humorous costume

paintings, a genre in which he excelled, though to many his art became a symbol for all that was most reprehensible in academic "subject" painting towards the end of the 19th century. His large canvases depicting young men and women in fanciful Empire costume under such titles as *In Love*, and *A Lovers' Quarrel*, were no more than large-scale magazine illustrations, and enjoyed great popularity as engravings. Probably his most enduring work will prove to be his illustrations, done as a young man, for the original editions of Dickens's *Great Expectations*, and *Our Mutual Friend*. Stone, who became A.R.A. in 1877 and R.A. in 1887, died March 24, 1921.

Stone Age. Term denoting the earliest phase of human culture, before the use of metals. It was adopted by Thomsen in 1836 when classifying Denmark's prehistoric implements into the threefold sequence of stone, bronze, and iron. But this primeval culture was more comprehensive than the term implies. It utilised wood, bone, horn, shells, and skins, besides witnessing the advent of articulate speech, firemaking, and the expression of the emotions in ritual and art. Hence it is more fittingly designated pre-metallic.

The European Stone Age is divisible into four phases: Eolithic, Palaeolithic, Mesolithic, and Neolithic. The oldest is held to be attested by crude implements revealing traces of artificial fabrication, such as those from the

Pliocene near Ipswich and the Red Crag of Foxhill, Suffolk. The Palaeolithic civilization, all within Pleistocene time, has been mapped out, especially in France, into well-defined cultures: Chellian and Acheulian form the lower, Mousterian the middle, and Aurignacian, Solutrian, and Magdalenian the upper division. A Chellian flint workshop was identified at Cromer in 1921.

The primal edged eoliths were universal tools, serving all purposes of splitting and scraping. In the ages before metallurgy was invented man learned to fashion, out of flint and other hard stones, scores of special tools, including chisels, awls, knives, lanceheads, bracers, saws, lamps, and palettes, besides spear-throwers, borers, pins, needles, beads, picks, hafts, harpoons, and cups in other materials. Some of these forms survived through the Mesolithic Azilian and kitchen-midden periods into the lake-dwellings, sepulchral mounds, and pit-villages of the Neolithic age.

This New Stone Age is commonly distinguished from its precursor as that during which many edged tools were made of stones other than flint and were ground and polished. Civilization owes to the Neolithic man the development of pottery and weaving, animal domestication, and navigation.

The later Neolithic Age witnessed the erection of massive stone monuments. These megalithic structures, of which many thousands still stand in Europe and N. Africa, show no trace of metal tooling. In Malta they reached a remarkable development in the temples of Hagier Kim, Mnajdra, and Hal-Tarxien, excavated by T. Zammit in 1920. Their builders ate the flesh of the ox, sheep, pig, and goat, as well as shell-fish, using the shells for personal ornaments.

The dispersion of Stone Age man spread his culture far and wide. It

is traceable in the prehistory of many Old World regions, remains being found in regions from the Atlas to Japan, from Siberia to Ceylon, which witnessed in their turn the advent of still higher levels of advance. Some peoples drifted into new homes, remote from the main cultural stream, where they remained in complete geographical isolation, e.g. Bushmen and Andamanese, Australians and Maoris, Fuegians and Eskimo. See Anthropology; Archaeology; Art: Prehistoric; Carnac; Cave Dwellings; Kitchen-Midden; Man. Consult The Ancient Stone Implements, Weapons and Ornaments

of Great Britain, J. Evans, 2nd ed. 1897; Prehistory, M. C. Burkitt, 1921; A Textbook of European Archaeology, R. A. S. Macalister, 1921; Stone Age Africa, L. S. B. Leakey, 1936; The Prehistoric Foundation of Europe, C. F. C. Hawkes, 1940; From Savagery to Civilisation, G. Clarke, 1946.

Stonechat (*Saxicola torquata*). Small British bird, belonging to the thrush tribe. In the male the

Stonechat, often found on British commons

plumage of the head, back, wings, and tail is black and white, with a bright reddish breast; while the female has a dusky brown head and back, and a black throat speckled with white and

red. The bird is about 5 ins. long. See Eggs colour plate.

Stone Circle. Megalithic monument comprising a series of menhirs (*q.v.*) enclosing a round, oval, or rectangular area. In France it is called a cromlech (*q.v.*). The largest British example, at Avebury, Wilts, was a circle of 100 menhirs enclosing two pairs of concentric rings. Other examples are Long Meg and her Daughters, Cumberland; Dance Maen, Cornwall; Stanton Drew, Somerset. They are numerous in N. Africa; Syria; India; Malay Archipelago (Borneo, Celebes); the Pacific (Gilbert Islands); and Peru. See Stanton Drew.

Stone-crop (*Sedum*). Popular name for a number of hardy, creeping plants of the family Crassulaceae. See Sedum.

Stone Fly. Name given to sombre-coloured insects of the order Plecoptera (Gk. *plekein*, to fold; *pteron*, a wing), with narrow membranous fore wings and broader folded hind wings. They are rarely found far from water, in which their immature

or nymphal stages are spent. Some 32 species are British.

Stonehaven.

Police burgh, seaport, and the co. town of Kincardineshire, Scotland. It stands on the North Sea and the Carron and Cowie rivers, 15 m. S. by W. of Aberdeen, and is served by rly. There are an old

and a new town and a small harbour; also amenities for summer visitors. Pop. 4,250. See Dunnotar Castle.

Stonehaven burgh arms

Wilts, England. The most imposing megalithic structure in Great Britain, it comprised integrally two concentric stone rows on a horseshoe plan, surrounded by two concentric stone circles. Now much impaired, it stands within a circular earth-

Stonehaven, Kincardineshire. The bay and old town built round the fishing harbour

work, 300 ft. across, opening towards the N.E. into an embanked avenue still 200 ft. long. Within this stands the Friar's Heel, a sarsen menhir or tertiary sandstone, 16 ft. high; at the earthwork opening, the so-called slaughterstone, 20 ft. long, lies prostrate.

The outer circle, 100 ft. across, comprised 30 sarsen uprights, 16 ft. high, and 3½ ft. apart, each with two tenons atop, into which was mortised a continuously dovetailed architrave of horizontal capstones, 2 ft. 8 ins. high. Nine feet within, an inner circle of menhirs, 6 ft. high, were mostly diabase bluestones. Within this arose a horseshoe of five trilithons, each of three sarsens, the two single-tenoned uprights supporting an independent capstone. The innermost pair of uprights are 21½ ft. high, the capstone 15 ft. long, 3½ ft. high. An inner horseshoe of bluestone menhirs enclosed the so-called altar-stone (A) of micaceous sandstone, 16 ft. long.

Of each series less than half remains standing, some being prostrate, some missing. The uprights, all embedded at varying depths in the chalk soil, were doubtless poised and imposed by means of earthen ramps and ropes. The sarsens, identical with the greywethers of Marlborough Downs, 14 m. away, were, after

Stonehenge. The ancient stone monument on Salisbury Plain, after its restoration in 1920, from the south-west. Top, plan, from the same point, showing original position of existing stones. A marks the Altar stone

rough dressing, transported thence by human labour. The igneous bluestones are erratic boulders, perhaps from a local ice-borne deposit, or brought from Pembrokeshire, 200 m. away. Sir J. N. Lockyer, regarding the monument as designed to mark the midsummer sun rising, calculated for it the date 1680 B.C.

On Dec. 31, 1900, one of the outer pairs with its capstone fell.

Stonyhurst College, Lancashire. South front of the public school, viewed from the lake. Founded at St. Omer, the school was moved to England in 1794

Restoration and concurrent excavations revealed many flint axes, with quartzite hammerstones up to 6 lb., and mauls up to 64 lb., besides antler picks. This evidence pointed to a late Neolithic date, anterior to metal tools. The earthwork was apparently of older date. The property was presented to the nation in 1918, and further excavations and restorations were carried out from 1920. See Trilithon; Woodhenge.

Bibliography. Stonehenge, W. M. F. Petrie, 1880; S. and its Earth Works, E. Barclay, 1895; Archaeologia, lxviii, W. Gowland, 1901; S. Astronomically Considered, Sir J. N. Lockyer, 1906.

Stonehouse. Parish and town of Lanarkshire, Scotland. It is 18 m. S.E. of Glasgow by rly., and has textile and coal mining industries. Pop. 3,704.

Stoneleigh. Parish and village of Warwickshire, England. It is on the Avon, about 2 m. E. of Kenilworth. Stoneleigh Abbey, the seat of Lord Leigh, dates from the early part of the 18th century, but embraces portions of a 12th century monastery founded by Henry II. These include a number of Norman doorways and the S. aisle and transept of the abbey church, and in the crypt are remains of a piscina and ambry. Its W. front is in the Classic style, and was built by the 3rd earl in 1720. It contains a fine collection of portraits and paintings by Lely, Wynants, Holbem, Gainsborough, and other celebrated artists.

Stone Money. Currency tokens formerly used by the Micronesian people of Yap, one of the Caroline

islands. The native name was fei. They were solid limestone disks, from 1 ft. to 12 ft. in diameter, with square holes for pole-transport. Small change was furnished by flat pearl shells, down to 5 ins. in diameter.

Stone Monuments. Term denoting a homogeneous class of prehistoric structures of unhewn or slightly worked stones. Often massive, they are preferably

termed megalithic (*g.v.*). While some arose in the Neolithic environment, they also pertain to early Bronze-age Europe. Their construction was continued through the early Iron age, and survives in India and elsewhere. See Beehive Structure; Cromlech; Dolmen; Druid Circle; Menhir; Monolith; Stone Circle; Stonehenge.

Stonesfield Slate. In geology, name given to a limestone of the Jurassic period. The stone is not really a slate, but is so called from the fact that it is thin bedded, and can be used for many purposes like true slate.

Stoneware. Class of earthenware glazed with salt. It was made in central Europe during the 16th century, and thence found its way to England, where it was first made at Fulham. According to legend, the process was a new discovery about 1652. On a farm in Staffordshire an earthen pot containing salt and water was being heated. Through neglect the pot boiled dry, and became red hot; when cool it was found to have become coated with a hard, fine glaze. See Pottery.

Stonor. Village of Oxfordshire, England. It is 14 m. N.W. of Henley-on-Thames. Stonor Park is the seat of Baron Camoys, the head of an old R.C. family, the peerage dating from 1264. In the house, the Jesuit Edmund Campion set up his printing press in the reign of Elizabeth. The upper part of Wren's original spire of S. Bride's, Fleet Street, London, stands in the grounds of Park Place. Here also is found Temple Coombe, a druidic temple found in Jersey and brought to Park Place in 1785. to

honour Gen. Conway, governor of the Channel Islands.

Stonyhurst College. R.C. public school. In Lancashire, about 4 m. N.W. of Whalley, it ranks as the chief school of its kind. It is the successor of a school founded at St. Omer about 1592 by the Jesuit, Robert Parsons. This was moved to Bruges in 1762, and to Liège in 1773. When the French Revolution drove it to England, a Lancashire squire gave his house at Stonyhurst for the school, and there it has been ever since 1794. The original buildings have been much extended, and in addition to the usual school building, laboratories, etc., it has a magnificent library and a museum. There is accommodation for about 400 boys, who are divided into the higher line and the lower line, and there is a preparatory school. The head is the rector, and most of the masters are priests.

Stonyhurst College arms

Stony Stratford. Town of Bucks, England. Formerly a market town, Stony Stratford stands on the Ouse and the Grand Union Canal, 8 m. N.E. of Buckingham and 2 m. from its rly. station, Wolverton. The churches of S. Mary Magdalene and S. Giles were rebuilt in the 18th century, but each incorporates some part of an earlier structure. An Eleanor cross erected here was pulled down in 1646. The industries include engineering works. Pop. 2,000

Stool (A.S. *stól*, seat). Small seat without a back. One of the first articles of furniture to be made, it is seen in a variety of forms in old Egyptian sculptures. It is usually a square or round block supported by three or four legs, and frequently upholstered. It varies in size from a foot-stool to a high seat. (See illus. p. 7808; also Faldstool; Furniture.)

The stool of repentance was a pew or seat in a Scottish church, elevated above the congregation, upon which those guilty of moral offences were made to stand. It disappeared from use before the end of the 18th century.

Stoolball. English game, regarded as the ancestor of cricket. A stool was placed on the ground and defended by a player with his hand, afterwards with a stick, against a ball tossed at it by his opponent. Every time the ball was hit away it counted one to the

batsman; if it hit the stool he was out. The game has been revived in some country districts of England.

Stop. Act of stopping, a hindrance. In punctuation (*q.v.*), a full stop or full point marks the end of a sentence. A stop in music has several meanings. (1) In the organ, it means a complete set of pipes of the same quality and answering to the same control, *c.g.* an open diapason or an oboe. It is so called because, so long as the stop handle is not drawn, the way for the wind to flow into any of the pipes, when their respective keys are depressed, is stopped. When it is drawn out the way is open. (2) The harpsichord was often provided with stop handles, either above or at the side of the manuals. They affected the action so as to produce different tone effects, or to bring into play an octave string. (3) A string instrument player stops his strings by pressing the fingers upon them.

Stopes, MARIE CARMICHAEL (b. 1880). British eugenicist, palaeontologist, and writer. Born in Edinburgh, Oct. 15, 1880, she was educated at London and Munich universities, graduated Ph.D., and was the first woman placed on the science staff at Manchester

Marie Stopes,
British eugenicist

university, 1904. An expert on fossil plants, she went with a scientific mission to Japan in 1907, and later wrote standard books on plants of the ancient world. In England in 1918 she married the aircraft designer, H. V. Roe. With him she founded in 1921 a clinic for birth-control, and began a determined fight for liberty of expression on this topic which aroused strong opposition and involved her in several lawsuits. This pioneer in frank statement upon sexual

hygiene wrote widely read books with such titles as *Married Love*, 1918; *Radiant Motherhood*, 1920; *Contraception*, rev. ed. 1931; *Marriage in My Time*, 1935. Marie Stopes was also a novelist, playwright (Our Ostriches, Court Theatre, 1923), no mean lyric poet (*e.g.* The Bathe, 1946), and a eulogist of the verse of Lord Alfred Douglas. Under the pseudonym Erica Fay she wrote a children's play *Buckie's Bears*, produced at the Royalty, Dec. 7, 1931, and five subsequent Christmasmas.

Stop Order. In English law, means whereby any person having a claim to or lien on a fund in court, or on stocks or shares standing to the credit of any cause in the name of the paymaster-general, may obtain an order stopping the fund being paid out, or the stocks or shares transferred to anybody, without notice to him.

Stop Watch. Watch indicating fractions of a second by a hand that may be stopped instantly by pressure on a spring or catch. It is used in timing races, to record an interval between two successive observations, or to mark the exact time of an observation without looking away from the object observed. *See* Watch.

Stork. Family of large birds (*Ciconiidae*) belonging to the heron

group, but distinguished by many minor features of structure. They have long, straight, and sharp beaks, and long legs. The white stork (*Ciconia ciconia*) is common in Central Europe, but occurs very occasionally in the E. counties of England. The plumage is white, with the exception of some black feathers on the wings; the beak

Stork. White stork, common in Central Europe, where it builds its nest on the chimney tops, as shown at top

and legs are red; and the total length is about 43 ins. The species is migratory, the winter being passed in Africa, where it ranges from Algeria to Cape Colony.

This stork usually builds its nest on a house roof or church tower. The same nest is used year after year, more sticks being added each season till it often reaches a great size. The food consists of reptiles, small mammals, insects, and offal; and the bird, thus useful as a scavenger, is more or less protected in Holland and Germany.

The black stork (*C. nigra*) is smaller and much less common; but is widely distributed in Central and S. Europe, in Asia, and in some parts of Africa. It occasionally occurs as a straggler in Great Britain, and is found chiefly in

swamps, where it nests in the trees. *See* Adjutant; Jabiru; Marabou.

Stork's-bill (*Erodium cicutarium*). Annual or biennial herb of the family Geraniaceae. It is a native of Europe, W. Asia, and N. Africa. It has oblong leaves divided into many acutely lobed

Stool. 1. Carved oak, late 16th century. 2. Oak, c. 1650. 3. Walnut with woolwork cover, early 18th century. *See* text in p. 7807

segments. The rosy flowers are clustered in small umbels. The long tapering fruits, when ripe, split into five segments lined with hairs, each segment forming a tail to a seed. The tail coils into a spiral and the hairs stand out laterally. When the seed falls to the ground the alternate lengthening and shortening of the spiral, under the influence of the dryness and moisture of the atmosphere, forces it into the earth.

Storm. Term commonly used for any violent disturbance of the atmosphere. High winds or gales, included under the headings of storms, occur suddenly at irregular intervals. Storms are of three main classes. First there are the depressions of extra-tropical latitudes. These are great eddies of the prevailing westerlies, whose diameters range from 500 to 1,000 m. or more. Such storms occur in both hemispheres in the latitudes of the westerlies, and are accompanied by changeable winds, great masses of cloud, and much rain or snow. To the second class of storms belong the violent tropical cyclones, hurricanes, and typhoons. These are accompanied by dense masses of clouds and torrential rains. In the third class may be put tornadoes, water-spouts, and thunderstorms and squalls. See Cyclone; Depression; Hurricane; Squall.

Storm, THEODOR WOLDSSEN (1817-88). German poet and novelist. He was born at Husum, Slesvig, studied jurisprudence at Kiel and Berlin, and became a judge. He died July 3, 1888. A prolific writer of poems and stories, he is best known by *Immensee*, 1850; *Gedichte* (Poems), 1852; *Psyche*, 1875; *Bei Kleinen Leuten* (Among Little People), 1887.

Stormont. Site of the parliament buildings of N. Ireland in Belfast. The former estate of Stormont Castle is to the E. of the city on the Newtownards road; it was purchased in 1921 by the government, and the foundation stone of the new buildings was laid in 1928. The U.K. parliament contributed the cost of approximately £500,000. There are chambers for the senate and lower house, and 157 other rooms. In the drive stands a large statue of Carson. See illus. p. 1051.

Stormovik. Russian military aircraft. It was developed during the Second Great War for low level attack against German armoured units. A single-seater machine with a wing span of 32 ft., it was armoured against light A.A. fire and mounted a 37-mm. cannon and, in later versions, six rocket guns.

It had a top speed of 260 m.p.h. and exceptional manoeuvrability at low levels.

Storm Trooper. Member of the *Sturm-Abteilung*, the former Nazi party army in Germany. Organized in 1922 ostensibly for the protection of speakers at party meetings, the storm troopers were in fact intended as the army of a Nazi revolution. They were tolerated by the authorities as one of the many substitutes for the army forbidden by the Versailles treaty. The distinguishing uniform of the organization was a brown shirt. When Hitler came to power in 1933, it assumed an official character, but lost much of its influence after the purge of 1934, when its paramount position was taken by the S.S. troops. In 1936 the storm troops were reorganized to provide pre-military training on a spare-time basis. The movement had a maximum strength of 2,000,000 men. Besides enforcing the anti-Jewish laws, it furnished guards at concentration camps. Put on trial at the Nuremberg tribunal in 1945-46, it was acquitted.

Stornoway. Seaport and police burgh of Lewis, Scotland. Standing on a large modern harbour on the E. side of the island, it is 180 m. N.N.W. of Oban and is the chief town of the Outer Hebrides. The castle, in Tudor style, is used as municipal buildings. Stornoway is a centre of the herring fishery. Founded by James VI, it is the biggest town in Ross-shire, with pop. 3,771, and was the birthplace of the explorer Mackenzie.

Storrs, SIR RONALD (b. 1881). British administrator. Born Nov. 19, 1881, he was educated at

Sir Ronald Storrs, British administrator

Charterhouse and Pembroke College, Cambridge. He worked for the Egyptian government from 1904 and in 1909 became Oriental secretary to the British agency at Cairo. Assistant political officer to the Anglo-French mission, 1917, and liaison officer for the mission in Bagdad and Iraq, he performed valuable work, and was made military governor of Jerusalem, 1917-20, civil governor, 1920-26. Having governed Cyprus for the next six years and N. Rhodesia for two, Sir Ronald in 1934 retired from tropical service. He was special correspondent for the *Sunday Times* in 1942-43, lec-

tured for the British Council, broadcast on foreign affairs, and wrote commentaries on the Second Great War. He was knighted in 1924. His autobiographical *Orientations*, 1937, was republished in final definitive ed. 1945.

Storting (great council). Name of the legislative body of Norway (*q.v.*). It consists of 150 members chosen by universal suffrage every fourth year.

Story, JOHN (c. 1510-71). English martyr. An M.P. in 1547, he came into prominence by his opposition to the Act of Uniformity in 1548. He was made chancellor of the dioceses of London and Oxford, and dean of arches in 1553. A vigorous heretic-hunter under Queen Mary, he was arrested in 1563, during Elizabeth's reign, but escaped to Flanders. Decey to England in 1570, he was executed at Tyburn, for high treason, June 1, 1571. He was beatified by the R.C. Church in 1886.

Story, JOSEPH (1779-1845). American jurist. Born at Marblehead, Massachusetts, Sept. 18, 1779, and educated at Harvard College, he was elected to the state legislature, 1805, and to congress, 1808. Associate justice to the supreme court, 1811-45, he died Sept. 10, 1845. He wrote *Commentaries on the Constitution of the United States*, 1833.

Joseph Story, American jurist

Story, SHORT. The development of this branch of fiction is described under Short Story.

Story of an African Farm, THE. Novel by Olive Schreiner (*q.v.*), published, under the pseudonym of Ralph Iron, in 1883. It is remarkable for its vivid descriptions of life on a South African ostrich farm, its striking presentation of the problems troubling a strong intelligence in restricted circumstances, and its deep pathos.

Story of San Michele, THE. Autobiography of Axel Munthe (*q.v.*). This vol. of memoirs was published in 1929, and takes its title from the author's villa on Capri where the book was written. The book was one of the most widely read autobiographies of its time.

Stössel, ANATOLY MIKHAILOVITCH (1848-1915). Russian soldier. Entering the army in 1866, he became a general in 1899. During the Russo-Japanese War, 1904-05, he was in command of the fortress of Port Arthur, and during the

progress of the siege was given credit by the outside world for what appeared to be a most heroic defence. When the fortress fell, however, the matter took a different complexion, and in 1908 he was tried by court-martial and sentenced to death. The sentence was commuted to ten years' imprisonment, but after fifteen months he was released because of ill-health. He died Jan. 17, 1915.

Stothard, THOMAS (1755-1834). British artist. Born in London, Aug. 17, 1755, he studied at the

Thomas Stothard,
British artist
After J. Jackson

R.A. schools. He painted subject pictures in oils, particularly for Boydell's Shakespeare Gallery, but his real talent lay in illustrative design. Richardson's novels, and

many other classics, were illustrated by him, with drawings of character and grace. More than 3,000 of these drawings were published. He became A.R.A. in 1791, R.A. in 1794, and librarian in 1812. He died in London, April 27, 1834. See Portland, 3rd Duke of.

Stott, THOMAS (1755-1829). Irish poet. Born at Hillsborough, co. Down, April 21, 1755, he developed a facility for verse at an early age. Settling at Dromore, co. Down, he made a considerable fortune in the linen-bleaching business. His early poems, published in various local organs, and usually signed Hafiz, evinced decided republican views. His opinions became more conservative with advancing years. He is chiefly remembered for The Songs of Deardra, 1825. Died April 22, 1829.

Stott, WILLIAM (1858-1900). British artist. Born at Oldham, he

Thomas Stott,
Irish poet
From a painting of
c. 1800

studied under Gérôme in Paris, and for some time resided in France, chiefly near Fontainebleau. Ultimately he settled in London, where his imaginative figure-

subjects attracted great attention. He was also a good painter of landscape, especially mountains, and a portraitist. Stott of Oldham, as he was called, died suddenly at sea, Feb. 25, 1900.

Stoughton, JOHN (1807-97). British divine. Born at Norwich, Nov. 18, 1807, he was educated

John Stoughton,
British divine

at the grammar school there. Having abandoned the career of a lawyer, he was trained at Highbury for the Congregational ministry and became, in 1833, minister of a church at Windsor. In 1843 he moved to Kensington, and remained there until 1875. In 1856 he was chairman of the Congregational Union, and from 1872 to 1884 was professor at New College, Hampstead. Also known as an historian, he wrote Ecclesiastical History of England, 1867-70, and other works. Stoughton died Oct. 24, 1897. His eldest son, Thomas Wilberforce Stoughton (1842-1917), founded with M. H. Hodder the publishing firm of Hodder & Stoughton (q.v.). Consult Recollections of a Long Life, J. Stoughton, 1894.

Stour. Name of several English rivers. One is in Kent; rising to the N. of Hythe, it flows N.W. to Ashford and then N.E. past Canterbury to Stourmouth, where it receives the Little Stour, and, after a further winding course, enters Pegwell Bay by an estuary at Sandwich. Its length is 40 m.

Another Stour rises in several headstreams which unite near Haveringham, whence it passes E. between Essex and Suffolk to the N. Sea at Harwich. Its length is 47 m., and it is navigable to Sudbury.

A third river of this name rises 5 m. S.W. of Banbury, Oxon, and flows W. and N.W. to the Avon, near Stratford-on-Avon. Its length is 20 m. Yet another Stour rises near the S.E. boundary of Somerset and flows 55 m. S.E. through Dorset and Hants to the Avon at Christchurch.

A fifth river rises near Halesowen and flows W. past Stourbridge into Staffs, and then S. through Worcestershire, joining the Severn at Stourport. It is 20 m. long.

Stourbridge. Mun. borough and market town of Worcestershire, England. It stands on the Stour, 144 m. N.W. of London and 12 m.

W. of Birmingham, and is served by rly. and canal. The buildings include S. Thomas's church, S. Mary's church, town hall, endowed school, corn exchange, and market house. The town is noted for its fine clay, which is made into firebricks, and also for its glass, the latter industry having been introduced about 1600 by refugees from Hungary. Hardware and leather are manufactured, and around are coal mines. At Kinver Edge, 4 m. away, is a stretch of moorland used as a public park. The old name of Stourbridge was Storebrugge. From 1888 to 1914, when it was made a borough, it was an urban dist., and before then was in the parish of Old Swinford. In

Stourbridge, Worcs. View showing
the town hall and Market Street

1933 the urban district of Lyo and Wollescote and the parish of Pedmore in Bromsgrove rural district were added to the borough. Pop. 36,290.

Stourbridge (OR STURBRIDGE) **Fair.** Fair held at Barnwell, Cambridge, and for long perhaps the most important in England. It probably began in the 12th century, and the earliest known charter for it was given early in the 13th. Held in Oct. and Nov., it was opened by the vice-chancellor, and the university had certain rights over it. The main articles sold were cheese, wool, timber, and horses. Defoe described it in his Tour through Great Britain, 1724-26. The name is that of a chapelry, 1 m. N.E. of Cambridge proper. It had a hospital for lepers, of which the chapel, a Norman building, remains.

Stourport. Urban dist. and market town of Worcestershire, England. It stands at the junction of the Stour and Severn, and is the terminus of the Staffordshire and Worcestershire canal, being 4 m. S.W. of Kidderminster and 12 m. N. of Worcester by rly. It has

William Stott,
British artist

manufactures of carpet and iron ware and a trade along the river and canal. There are petrol storage depots and a large electrical generating station. Stourport owes its existence to the opening of the canal about 1780. Market day, Sat. Pop. 9,500.

Stout. Details of the manufacture of this malt liquor are given under Brewing.

Stove. Primarily a fuel-burning apparatus for warming and/or cooking, built so as to be independent of brickwork. Several patterns are specifically designed to burn special fuels, such as anthracite and lignite, and others trade wastes such as sawdust. In the simplest form a closed-top cylinder of cast iron is provided with a primary air inlet at floor level immediately below a fire-bar grating, and with a smoke-pipe connexion near the top. This pattern heats largely by radiation, and may be opened only to replenish the fire. Others may remain open when in use, and these are often fitted with a perforated casing that greatly assists convection heating. In all patterns the rate of combustion is controllable by altering the size of the primary air opening.

Stoves are widely used in rural areas, and usually incorporate a top or back oven. In urban areas a coloured enamel casing of a stove may conceal a hot water boiler serving several radiators in addition to tap water. Solid-fuel heating and cooking stoves have been largely superseded by gas, electric, and oil burning units, and by heavily insulated heat storage cookers. These are often fitted with thermostatic controls.

Stove House. In horticulture, a structure for the rearing of plants which require the steady maintenance of a high temperature. The temperature should range from a minimum of 60° up to at least 80° F., the winter day maximum being 70° and the summer day minimum 65°. The heat is usually supplied by hot-water pipes, and, to prevent dryness of atmosphere, shallow iron pans filled with water should be stood

upon the pipes at intervals. Over some of the pans plants requiring rapid forcing can be placed in receptacles filled with coconut refuse, tan, etc., the shallow tanks providing the necessary bottom heat. *See* Greenhouse; Hothouse.

Stow, JOHN (c. 1525-1605). English antiquary. Born in London, son of Thomas Stow, tallow chandler, he became

John Stow,
English antiquary
From a print by
G. Vertue

a tailor at Aldgate, took his brother Thomas as apprentice, but from about 1560 devoted himself to antiquarian research. A great book collector, he was reported to the authorities in 1569 as possessing 38 dangerous works of superstition or "papistyry." Straited in circumstances in his later life, but honoured, notably by Archbishop Parker, for his industry and learning, James I granted him patents in 1603 and 1604 to ask and take benevolence. He died of stone colic, and was buried, April 8, 1605, in the church of S. Andrew Undershaft, where a monument was erected to him.

Stow's works include notable summaries of old English chronicles, but he is chiefly remembered for his valuable Survey of London, 1598 and 1603, the chief authority on the city as it was in his own time. The Survey was edited and enlarged in 1618, 1633, 1720, and 1754. *Consult* Edition of the original text, with Life and Notes, C. L. Kingsford, 2 vols., 1908.

Stowe. Historic mansion, now the home of a public school, 3 m. N. of Buckingham, England. Over 900 ft. in length, with superbly decorated rooms, richly appointed and surrounded by vast grounds abounding in temples and statuary, it was mainly built by Sir Richard Temple about 1660, added to by his successors, and was the seat of the dukes of Buckingham and Chandos until 1889, when it passed to the 3rd duke's daughter, the baroness Kinloss, by whose order

it was sold in 1921. It was opened as a public school in 1923, and in 1928 Queen Mary laid the foundation stone of the school chapel, built to designs by Sir R. Lorimer. The original building was the nucleus of the school, which grew rapidly, holding eventually some 500 boys. The Stowe MSS., bought by the marquess of Buckingham in 1803, were acquired by the British Museum in 1883.

Stowe, HARRIET ELIZABETH BEECHER (1811-96). American writer and abolitionist. Born in

Litchfield, Conn., June 14, 1811, the daughter of Lyman Beecher (q.v.), the preacher, and the sister of Henry Ward Beecher (q.v.).

Harriet Beecher Stowe
she was educated at Litchfield Academy and at Hartford. She accompanied her father to Cincinnati in 1832, and in 1836 married one of his assistants, the Rev. Calvin E. Stowe, a strong anti-slavery advocate.

She had no personal experience of slave-owning society; but the novel *Uncle Tom's Cabin*, which made her name, helped materially in the abolition of slavery in the U.S.A. It appeared as a serial in *The National Era*, of Washington, between June, 1851, and April, 1852, and was published in book form in Boston in 1852. Mrs. Stowe visited Europe in 1853, when she spoke in favour of emancipation of the slaves, and in 1856 pressed it anew in *Dred: a Tale of the Dismal Swamp*. In 1869 Mrs. Stowe stirred up a bitter controversy in England by her article on Lord and Lady Byron, in *Macmillan's Magazine*, and by publishing in *Lady Byron Vindicated* the nature of the charges brought against the poet by his wife. She died at Hartford, Conn., July 1, 1896. *Consult* Lives, by her son, 1889; C. Gilbertson, 1937; Crusader in Crinoline, F. Wilson, 1942.

Stowell, WILLIAM SCOTT, BARON (1745-1836). British lawyer. Born at Heworth, Durham, Oct. 17, 1745, he was educated at Newcastle grammar school and Corpus Christi College, Oxford. He became Camden lecturer on ancient history at Oxford and a barrister, and in 1780 began to practise in London. In 1788 he was made a judge, and during 1798-1827 was

Stowe, Buckinghamshire. North front of the mansion, now a public school

Baron Stowell,
British lawyer
After T. Phillips

judge of the court of admiralty. Having sat in the house of commons for Oxford university, he was made a baron in 1821. He died Jan. 28, 1836. Stowell

is regarded as the founder of British prize law and one of the great authorities on international law.

Stowmarket. Market town and urban dist. of Suffolk, England. It stands on the Gipping, 12 m. N.W. of Ipswich and has a rly. station. The chief buildings are the old church of SS. Peter and Mary and the corn exchange. The old vicarage has associations with Milton. There are manufactures of chemicals and agricultural implements, and a trade in corn. Market day, Thurs. Pop. 7,500.

Stow-on-the-Wold. Market town of Gloucestershire, England. It stands on the Fosse Way, at an

Stow-on-the-Wold, Gloucestershire. View of this market town in the heart of the Cotswolds

alt. of 765 ft., 18 m. E.N.E. of Cheltenham, with a rly. station. There is an old church and in the market place a 14th century cross. Horse and cattle fairs are held. Pop. 1,800.

Strabane. Market town and urban dist. of Tyrone, N. Ireland. It stands on the Mourne, near where it joins the Finn to form the Foyle, 14 m. S.S.W. of Londonderry and 161 m. N.W. of Dublin, with both of which places it has rly. connexion. Industries include iron foundries and shirt and underwear factories, and there is a trade in agricultural produce. Across the river, which here constitutes the boundary with Eire, is Lifford. Strabane had a castle in the 16th century and sent two members to the Irish parliament until 1800. A canal connects it with the Foyle. Market days, Tues. and Sat. Pop. 5,600. *Pron.* Str**ˈ**bann.

Strabismus (Lat. *strabus*, squinting). Medical term for the defect of the eyes known as squinting (*q.v.*).

Strabo (c. 63 B.C.-A.D. 19). Greek geographer. Born in Amasia, Pontus, he travelled extensively, and in 29 B.C. settled in Rome, where he lived until his death 47 years later. He was the author of two important works: (1) *Historical Memoirs*, in 46 books, a continuation of Polybius from 146 B.C. to the death of Caesar, lost with the exception of some fragments; (2) *Geographica*, in 17 books, nearly all preserved. It is a valuable work, partly based upon his personal experiences, and, after that of Ptolemy, is the chief authority on ancient geography. Books 3-10 are devoted to Europe, 11-16 to Asia, and 17 to Africa.

Strabolgi, JOSEPH MONTAGUE KENWORTHY, 10TH BARON (b. 1886). British sailor and politician. Born March 7, 1886, he was educated at the R.N. Academy, Winchester, and in H.M.S. Britannia, entering the Royal Navy, 1902. He served in the First Great War, became lieutenant-commander, 1916, and retired, 1920. He entered politics, and was Liberal M.P. for Central Hull, 1919, transferring his allegiance to the Labour party, 1926, and losing his seat in the general election of 1931. Commander Kenworthy succeeded his father

as 10th baron, 1934, and was opposition chief whip, house of lords, 1938-42. As a politician he established a reputation as an indefatigable questioner of ministers. His many publications, chiefly on naval matters, included *Statesmen and Others* (autobiography), 1933; *The Battle of the R. Plate*, 1940; *Singapore and After*, 1942; *Sea Power in the Second Great War*, 1943; *Conquest of Italy*, 1944.

Strachey, (EVELYN) JOHN (ST. LOE) (b. 1901). British politician and writer. Son of John St. Loe Strachey (*q.v.*), he was born Oct. 21, 1901, and educated at Eton and Magdalen College, Oxford.

Lord Strabolgi,
British politician

He was Labour M.P. for Aston from 1929 to 1931, when he resigned from the Labour party, joining for a short time Sir O. Mosley's New party.

In 1945, having rejoined the Labour party, he became M.P. for Dundee (Dundee W. from 1950). He was under-secretary for air until 1946, then minister of food. In 1950 he became secretary for war. He wrote *The Coming Struggle for Power*, 1932; *The Menace of Fascism*, 1933; *The Nature of the Capitalist Crisis*, 1935; *The Theory and Practice of Socialism*, 1936; *A Programme of Progress*, 1939; *Post D (A.R.P. Experiences)*, 1941. During the Second Great War, as Sqn. Ldr. Strachey, he became widely known as a broadcaster.

Strachey, (GILES) LYTTON (1880-1932). British writer. A son of Sir Richard Strachey (*q.v.*), he was born March 1, 1880, and educated at Trinity College, Cambridge, where he first turned to the study of history. His first book was *Landmarks of French Literature*, 1912; but it was a volume of biographical essays, *Eminent Victorians*, 1918, which brought him prominence. Queen Victoria, which followed in 1921, aroused wide controversy. Later he wrote critical studies of Pope, Voltaire, and others, as well as *Elizabeth and Essex*, 1928, which was a lively picture of a completely different type. He died Jan. 21, 1932. Strachey may be regarded as the founder of a new school of biographical writing, which was in reaction against the uncritical adulation of most official biographies. He had a malicious wit and a brilliant sense of satire. An estimate of his work by Max Beerbohm appeared in 1943.

Strachey, JOHN ST. LOE (1860-1927). British journalist. Second son of Sir Edward Strachey, 3rd Bart., he was educated at Balliol College, Oxford. He edited *The Cornhill Magazine*, 1896-97, when he became editor and proprietor of *The Spectator* (*q.v.*). He was a strong defender of free trade,

John Strachey,
British politician

Lytton Strachey,
British writer

while another cause he had at heart was the maintenance of good relations between England and America. His many books included *The Manufacture of Paupers*, 1907; *Problems and Perils of Socialism*, 1908; *Practical Wisdom of the Bible*, 1908. He died Aug. 26, 1927.

Strachey, Sir RICHARD (1817-1908). Anglo-Indian administrator. Born at Sutton Court, Somerset,

Sir R. Strachey,
Anglo-Indian
administrator

July 24, 1817, he entered the service of the E. India company in 1834. In 1846 he served with distinction against the Sikhs, and afterwards explored in the Himalayas, paying special attention to botany and geology. In 1856 he became a secretary in the Indian public works department, of which he was made head in 1862. He did valuable work in developing rlys. and irrigation. With his brother John he wrote *The Finances and Public Works of India*, 1882. In 1897 he was made a G.C.S.I. He died Feb. 12, 1908.

Stradivari, ANTONIO (c. 1644-1737). Italian violin maker. Born at Cremona, and apprenticed to Nicholas Amati, he at first modelled his instruments on those of his master, but about 1694 he adopted larger proportions, and became more independent in his methods. For a long time he seems to have experimented, but from about 1700 his instruments show that he had arrived at a definite conclusion as to the true proportions of a fine violin.

Upon the instruments of his maturest period rests his fame as indubitably the greatest of all violin makers. In the course of his long life, Stradivari made well over a thousand instruments, including violas and violoncellos, many of which are still extant, and the most celebrated of which are distinguished by particular names, such as *Le Messie*, *La Pucelle*, the *Dolphin*, etc. They are so much valued that large sums are paid whenever a "Strad" comes into the market. The finest specimens possess a rich full tone, but not all

J. St. Loe Strachey,
British journalist
Russell

his work is equally good, some of his early instruments in particular suffering from the use of inferior material at a time when he could not afford to buy better. On his labels Stradivari adopted the usual custom, and Latinised his name as Antonius Stradivarius. He died Dec. 18, 1737. See *Violin*; consult also *Stradivari: His Life and Work*, W. H. and A. F. Hill, 1902.

Strafford, EARL OF. British title borne by the families of Wentworth and Byng. The title was created in 1639 for Thomas Wentworth, the statesman, and became extinct when his son died in 1695. It was revived in 1711 for another Thomas Wentworth, Lord Raby, who was British minister at The Hague, 1711-14, and represented his country at the Congress of Utrecht. It remained with his descendants until the 5th earl died without sons in 1799. In 1847 Sir John Byng was made earl of Strafford, having been a baron since 1835. He was a great-nephew through his mother of the 4th earl, and was a military commander through the Peninsular War and at Waterloo. His descendants still hold the title, Edmund Henry Byng (b. Jan. 27, 1862) succeeding as 6th earl in 1918. The family seat is Wrotham Park, Barnet, and the earl's eldest son is known as Viscount Enfield.

Strafford, THOMAS WENTWORTH, EARL OF (1593-1641). English statesman. Born in London, April 13, 1593, of a great Yorkshire family, he was educated at St. John's College, Cambridge. He sat in successive parliaments under James I, and was the most powerful leader of the parliamentary opposition to Charles I and to

Buckingham. The critical year of his career was 1628, when he was active in promoting the *Petition of Right*, but on desiring to modify it was supplanted by Eliot as leader of the opposition. Wentworth passed over to the king's side and was created viscount.

As president of the council of the north he exercised an arbitrary jurisdiction until in 1633 he transferred his energies to Ireland as deputy. Governing ruthlessly, with a strong hand and a clear head, and showing neither fear nor favour except where the interests of the crown were concerned, he brought Ireland such order as it had never before known. He used his deputyship to organize a military force which should be at the disposal of the crown.

By the intrigues of the queen and a clique of courtiers Wentworth's plans were repeatedly subverted. In 1639 he was created earl of Strafford, and vainly imagined that he had won over the king, but again Charles allowed himself to be led by the court party. The Long Parliament was summoned, and its first step (Nov., 1640) was to move for the arrest and impeachment of Strafford for high treason. Though he had urged the king to use his Irish troops against the warring Scots, this was obviously a fantastic charge. It was clear that on the evidence there was no possibility of procuring a verdict against Strafford, so the commons adopted the unprecedented course of passing a bill of attainder, condemning him to death. The bill required the royal assent, and in spite of his pledged word the king gave way. "Put not your trust in princes," exclaimed the great administrator, who on May 12, 1641, was beheaded on Tower Hill. "Black Tom the tyrant" died because he stood in the way of English constitutional development. Browning wrote a tragedy in verse on his last phase. Consult *Lives*, H. D. Traill, new ed. 1902; Lady Burghclere, 1931; C. V. Wedgwood, 1935; 2nd earl of Birkenhead, 1938; Strafford and Ireland, H. O'Grady, 1923.

munication with Burnie, on the N. coast of the island, and steamer service for Melbourne and Launceston. Pop. 800.

Strahlegg Pass. Alpine pass in Switzerland, in the Bernese Oberland. It connects the Grindelwald with the Grimsel Pass (*q.v.*) and reaches a height of 10,995 ft.

Straight, WHITNEY WILLARD (b. 1912). British administrator. Son of an American father, and of the future Mrs. D. W. Elmhirst, organizer of Dartington Hall, he was born Nov. 6, 1912, and educated at Lincoln school, U.S.A., Dartington Hall, and Trinity College, Cambridge. As a professional racing motorist he won international events and set up speed records. In 1934 he went into civil aviation, and during the Second Great War served in the A.A.F. and was an air A.D.C. to the king. He became managing director, 1947, and deputy chairman, 1949, of B.O.A.C.

Strain and Stress. Terms used in mechanics. Stress is the equal and opposite action and reaction which take place between two bodies, or two parts of the same body, transmitting force. In the first case it is called an external stress, and in the second an internal stress. The external forces, acting on any portion of a body in equilibrium, are balanced by the internal stress. A body is altered in shape or dimensions by the stress acting on it, and is said to be in a state of strain or to be strained.

There are three principal kinds of stresses: (1) tensile, (2) compressive, (3) shear, with three resulting strains: (1) extension, (2) contraction, (3) a side or shear. A rope being pulled is an example of a body in a state of tensile stress; a walking-stick being leant upon, of compressive stress; and a wire subjected to a simple twist, of shear stress. To subject a body to a uniform compression in all directions would require it to be immersed in a liquid medium itself under pressure. Stress is measured by the force exerted per unit area, *e.g.* dynes per sq. cm., or ft. lb. per sq. in. Strain is measured according to the type of deformation, *e.g.* as a change of length per unit length for a tensile strain or a change of volume per unit volume for a bulk strain. Hooke's law, first enunciated in 1676, is assumed to hold for small strains, and stated that stress is proportional to strain. The ratio $\frac{\text{stress}}{\text{strain}}$ is a constant for a given material and defines the modulus of elasticity (*q.v.*).

Strait. A narrow passage of water between two oceans or seas. Most straits have been formed by the sinking of the land, *e.g.* those of Menai, Dover, and Gibraltar.

Straits Settlements. Former British crown colony. It comprised Singapore, Malacca, and Penang, all adjacent to the Strait of Malacca. the Cocos Is., Christmas I., and Labuan. In 1946 the colony was abolished: Singapore, with Christmas I. and the Cocos Is., became a separate colony; Penang and Malacca became part of the union (later federation) of Malaya; Labuan became part of N. Borneo. See Borneo, British North; Malaya, Federation of; Singapore.

Stralsund. Dist. and seaport of Mecklenburg, E. Germany. The port is 80 m. E. of Lübeck, on an island in the Strelasund, an arm of the Baltic. Its suburbs are on the mainland. It was a rly. centre, and terminus of a ferry to Sweden. Interesting buildings were the churches of S. Nicholas (1276), S. Mary (1298), and S. James (1303), and the 13th century town hall, all damaged by bombs in the Second Great War. Industries included engineering, shipbuilding, and making chemicals and sugar.

Known as a town since 1234, Stralsund was a member of the Hanseatic League from 1278. From 1648 to 1807 it was under Swedish domination, and in 1815 it became Prussian, being made into a powerful fortress. The town's hero is Ferdinand von Schill, who in 1809 lost his life in trying to raise the populace against Napoleon. Captured May 1, 1945, by Rokossovsky's 2nd

White Russian army, it came within the Russian zone of occupation. Pop. (1935) 44,539.

Stramonium. In medicine, name given to the seeds and dried leaves of *Datura stramonium*, or the thorn apple. Its principal constituent is the alkaloid hyoscyamine, and it is given to relieve spasm in asthma.

Strand, THE. A London thoroughfare which runs W. from Temple Bar to Charing Cross. On island sites where the roadway divides are two old churches, both damaged by bombs in the Second Great War—S. Clement Danes, built by Wren, 1681, with tower by Gibbs, 1719, which was almost entirely destroyed; and S. Mary-le-Strand, by Gibbs, 1717, replacing a church of the same name of which Becket was rector, and near the site of the famous maypole, removed 1718. On the N. side is the front of the law courts, Gladstone statue, Australia House, Bush House South, the disused Gaiety Theatre, Strand Palace Hotel (on the site of Exeter Hall, *q.v.*), Vaudeville and Adelphi Theatres, Coutts's Bank, and offices of the govts. of Queensland, New Zealand, S. Rhodesia, and Tasmania, and Trafalgar Square tube station. On the S. are Aldwych tube station, King's College, Somerset House, the approach to Waterloo Bridge, Western Australia govt. office, Savoy Hotel and Theatre, Shell-Mex House, Tivoli cinema (built on the site of the former Tivoli music-hall), New South Wales govt. office, Halifax House, and Charing Cross rly. station and Strand tube station.

The Strand. Western section of this famous London thoroughfare that connects the City with Westminster, looking E.

Strand-on-the-Green, Chiswick. Picturesque Georgian houses on the Causeway, overlooking the R. Thames

In early times little more than a bank of the Thames, hence its name, the Strand was long the sole land route from the City to Westminster, was crossed by several bridges, was not effectively paved until the time of George III, and has undergone many changes since, though it remains one of the busiest London thoroughfares. To its first building of note, the Savoy palace, were added ecclesiastical inns and mansions of great nobles, recalled by local names. See *Adelphi*; *Aldwych*; *Holywell Street*; *King's College*; consult also *Annals of the Strand*. E. B. Chancellor, 1912.

Strandlooper (Dutch, shore runner). Prehistoric cave-dweller on the W. coast of S. Africa. Human remains and handiwork show the tribe to have been short and round-headed, apparently immigrant from N. Africa. See *Bushman*.

Strand Magazine, THE. British illustrated monthly. Published in London it was founded, Jan., 1891, by Sir George Newnes, with H. Greenhough Smith as editor. Giving high-class fiction and illustrated articles, it proved an instant success. Many famous writers were closely associated with the magazine during the first thirty years of its existence, e.g. Sir A. Conan Doyle, most of whose Sherlock Holmes stories first appeared in it, W. W. Jacobs, P. G. Wodehouse, and E. Nesbit; and among others who contributed serial stories were H. G. Wells, F. Anstey, Rudyard Kipling, Hall Caine. During the Second Great War the Strand appeared in pocket size. It ceased publication with its issue of March, 1950.

Strand-on-the-Green. Formerly a hamlet of Middlesex, now part of the bor. of Brentford and Chiswick. Strand-on-the-Green is a small district and gives its name to a road extending to Kew

Bridge; it is built along the N. bank of the Thames, opposite Olive Island, and was in earlier times a fishing village. The houses facing the river along the Causeway are notable examples of Georgian architecture. In the house named after him, Zoffany painted many of his "conversation pieces."

Strand Theatre. London playhouse, in Aldwych, W.C.2. It was opened as The Waldorf, May 23, 1905, under the management of the Schubert brothers, the first production being a revival of The Second Mrs. Tanqueray, in which Duse played the lead. Renamed The Strand in 1909, it staged many highly successful plays of varied types, e.g. Mr. Wu, 1913; Anna Christie, 1923; 1066 And All That, 1935; Judgement Day, 1937; Arsenic and Old Lace, 1942. The theatre seats 1,210.

An earlier theatre of this name stood in the Strand, four doors W. of Surrey St. Converted from a panoramic exhibition in 1831, it was licensed in 1836, and rebuilt 1882. Associated with the Swanborough family for many years, it closed in 1905.

Strang, HERBERT. Pseudonym of Charles J. L'Estrange (d. 1947) and George H. Ely, who collaborated under this name in writing adventure stories for boys. The ideas were invented by L'Estrange, Ely writing them up. Their first "annual," 1908, was the forerunner of many publications for children by the Oxford University Press, a firm with which both writers were associated.

Strang, WILLIAM (1859-1921). British painter and etcher. He was born at Dumbarton, Feb. 13, 1859, was educated at University College, London, and studied under A. Legros (q.v.) at the Slade school, London. He attained remarkable distinction as an etcher, ranging over a vast variety of subjects, and emulating Rembrandt's broad masses of light and shade; for the

grim imagery of certain conceptions he is indebted to Holbein. He became A.R.A., 1906, and R.A. a few months before his death, April 12, 1921.

Strange, SIR ROBERT (1721-92). British engraver. Born at Kirkwall, Orkney, July 14, 1721, he was trained as a lawyer at Edinburgh, but afterwards studied engraving in London. Involved in the Jacobite rising of 1745, he fled to Rouen, studied there and in Paris, and, returning to England in 1750, was knighted in 1787. As a line-engraver of Van Dyck and Titian he is probably unequalled. Died July 5, 1792.

Strangers' Gallery. In the British parliament, name given to galleries to which members of the public are admitted, not as of right, but as a favour. In the house of commons the gallery faces the Speaker's chair. The public, who usually obtain admission through members, are not admitted until after prayers, and anyone making a demonstration or disturbance of any kind is promptly ejected by the assistants of the serjeant-at-arms. Moreover, on the cry "I spy strangers" the Speaker rises and orders the gallery to be cleared. Part is reserved for distinguished strangers. See *Commons*; *Parliament*; *Privilege*.

Strangford, VISCOUNT. Irish title borne by the family of Smythe from 1625 to 1869. Sir Thomas Smythe, created viscount in 1625, was a landowner in Kent. His descendant, Percy (1780-1855), who became 6th viscount in 1801, was British minister in Brazil, Sweden, Turkey, Russia, and elsewhere. His eldest son George, 7th viscount (1818-57), was an author and a Tory M.P., 1841-52. One of the Young England party, he is portrayed in Disraeli's *Coningsby*, and is also notable as having fought in the last duel in England. When George's brother, Percy, 8th viscount, died 1869, his titles became extinct.

Strangford Lough. Inlet on the E. coast of co. Down, N. Ireland. It penetrates inland for about 26 m., and its W. shore is lined with numerous small islands.

Strangles. Infectious disease of horses, due to a micro-organism. Of universal distribution, it shows itself by the presence of a cough, a discharge from the nostrils, and a swelling of the glands between the jaws, with fever. It occurs chiefly in young horses. See *Horse*.

Strangulation (Gr. *strangalē*, halter). Death from constriction of the neck by a force other than

William Strang, British artist
Self-portrait

the weight of the body. Accidental strangulation occurs in a variety of ways. The suicidal kind is rare. Murder by strangulation is often effected by the assailant grasping the throat of his victim from behind. See Garrotte; Hanging.

Stranraer. Royal and police burgh and seaport of Wigtownshire, Scotland. It stands at the head of Loch Ryan, 7 m. N.E. of Portpatrick. There are rly. stations, a large tidal harbour, and regular steamer connexion with Belfast and Larne. The chief buildings in this commercial capital of Galloway are the old town hall and modern ones for public business. There are ruins of a castle. About 3 m. E. of the town is the seat of the earl of Stair, Lochinch, Castle Kennedy, with grounds which are remarkable for a collection of rare trees. Stranraer was made a burgh in 1596. Market day, Fri. Pop. 8,000. See Ryan.

Strasbourg (Ger. Strassburg). City of France, capital of Bas-Rhin dept., centre of the Alsace region, and now seat of the Council of Europe. It stands on the junction of the river Ill with the Rhine, 10 m. E. of the Vosges mts. A main rly. junction and airport, the starting point of the Rhine-Marne and Rhine-Rhône canals, it has a port served by those waterways and a branch of the Rhine, handling between 5 and 6 million tons of shipping yearly. It is noted for

Strasbourg arms

pâté de foie gras and other food preserves, and has motor car, metal, and tobacco factories and book publishing houses. It was the seat of special government departments created in 1919 for Alsace-Lorraine; also a fortified military centre. It is an R.C. bishopric. Pop. 175,515.

Established as Argentoratum by the Romans on the site of a Celtic village, Strasbourg is rich in historical buildings. The cathedral is a red sandstone Gothic pile, with a S. tower 465 ft. high. Building was started in 1015 and completed c. 1430. Here are some of the most famous medieval sculptures, a beautiful rose window, and a remarkable clock. Stained glass from the cathedral was recovered from a salt mine near Heilbronn after the Second Great War. Other churches are Old and Young S. Peter's, and S. Thomas's (13th-14th centuries), with monument to Marshal Saxe. The Frauenhaus, originally work-

Strasbourg, France. Place Kleber showing Temple Neuf on the left, and the cathedral, right. Left, west façade of the cathedral, begun in 1277

U.S. 7th army, recovered Strasbourg after a spectacular 18 m. dash through the Saverne gap. During the Ardennes counter-offensive, Eisenhower planned to strengthen the Allied line farther N. by withdrawing all but a few light elements from the neighbourhood of Strasbourg. French representations of the catastrophic political effects likely to follow in France a new loss of the city led him to modify his plan and keep Strasbourg adequately covered.

Strasser, GREGOR (1892-1934). German Nazi leader. By trade a chemist, he was born at Geisenfeld, Bavaria, May 31, 1892. He was sentenced with Hitler after the *putsch* of 1923 to 1½ years' detention, but released after his election to the Bavarian diet in May, 1924. In Dec. he was sent to the Reichstag, and at once was in charge of the Nazi party organization. Next to Hitler, Strasser was the outstanding figure in the movement until in 1932 he fell out with his chief for proposing to give up the revolutionary programme in exchange for the monies contributed by German industrialists. Strasser retired from political activities and accepted a directorship in the Schering chemical combine, but the vengeance of his former associates reached him, and he was assassinated in the "purge" of June 30, 1934.

Strasser, OTTO (b. 1897). A German publicist, brother of the above Gregor Strasser. He was born at Windsheim, Franconia, Sept. 10, 1897. A Socialist writer and editor, in 1923 he followed Gregor into the Nazi party; he edited its National Socialist Letters, and during 1926-30 was a director of the Nazi Kampf-Verlag, a publishing firm in Berlin. He clashed with Hitler in 1930 and founded a more revolutionary group, later known as the Black

shop of the builders (1357), now houses episcopal archives. The bishop's palace was built for Cardinal Rohan in 1728-41. Half-timber and gabled dwellings in the German style are the most interesting secular buildings. There are bridges of 13th and 14th century origin, and pompous official buildings of the German occupation, 1871-1919. The seat of a university (1567), Strasbourg has 20 libraries, 13 museums, two theatres, and the House of Europe (1950), built for the Council of Europe.

Historical associations start with the defeat of the Alemanni by the emperor Julian in 357. Strasbourg was a centre of German humanism and early adopted the Reformation. A free city from 1262, it fell under French suzerainty in 1648 and was annexed by Louis XIV in 1681. Taken by the Prussians after a siege in 1870, under the Versailles treaty of 1919 it went back to France.

The population was removed at the outbreak of the Second Great War, the city being only 2 m. from the Rhine. Captured on June 19, 1940, Strasbourg was completely Germanised, even street names and shop signs being changed. On Nov. 23, 1944, the French 2nd armoured div., spearhead of the

Front, which was ostracised as soon as Hitler assumed power in 1933. Strasser took refuge in Vienna, was deprived of German citizenship, and later went to Great Britain and Canada. His book, *The Structure of German Socialism*, 1932, and others written in wartime—*Hitler and I*, *Germany Speaks*, *Germany Tomorrow*—had widespread success. From 1947 he began to propagate a federalist policy based on religion and a regional outlook.

Strata Florida (Latinised from Welsh *Ystrad Ffŷr*, plain of the Ffŷr). Village and parish of Cardiganshire, Wales. It has a rly. station 5 m. N.E. of Tregaron. Four miles away, on the Teifi, are the ruins of the Cistercian abbey of Strata Florida, which when complete was one of the largest in Wales, and a centre of learning and statecraft. Founded in 1091 and partly destroyed in the 13th cent., it was dissolved by Henry VIII.

Strategic Air Force. Organization of the R.A.F. developed in the Second Great War for long-term planned offensive operations. It was distinct from the Tactical Air Force (*q.v.*), which worked in cooperation with the army, attacking targets as they presented themselves in the battle zones. The strategic air force was the spearhead of all three services, assailing ports, airfields, shipping, rlys., factories, etc., deep in enemy territory. Bombing German, Italian, and Japanese industrial centres was its main function, and its chief weapon was the heavy bomber.

Strategy (Gr. *stratos*, army; *ago*, lead). The art of war, whereas tactics is the method by which warfare is waged. Strategy is greatly hampered unless there is complete unity between political control and military command. This presents no great difficulty when one nation is concerned, but in the case of Allies neither political nor military unity can be easily achieved. In the early days of the world despotism often seized complete power and the consequent unity resulted in very fine examples of grand strategy. Alexander the Great, as tyrant of the Grecian states, became a complete despot, and his strategy stands as a model. The history of war shows that most great captains were despots: *e.g.* Caesar, Frederick the Great, Napoleon.

SECOND GREAT WAR. The outstanding feature on the outbreak of the Second Great War was the supremacy in land power possessed by the German armed forces. On

the sea her power was limited, and in the air her forces had been mainly restricted to army co-operation duties. German strategy was simple. She seized Austria, made a non-aggression pact with Russia to secure her eastern front, and conquered Poland. She then turned on France and overwhelmed her army. Strategically the Germans should most certainly have pursued their advantage and invaded Great Britain, but they failed in psychological appreciation of the position.

At that stage Great Britain had to consider future strategy. She could not attack Germany without landing on enemy soil, and she could not win the war without attacking Germany. Winston Churchill, who combined the offices of prime minister and defence minister, appreciated this situation and formed a h.q. to study combined operations. By far the most urgent need was for the special landing craft without which military forces could not land on enemy shores, but it was not until 1942 that construction of landing craft was given first priority.

Germany's strategy in Russia, which she had invaded in 1941, was during 1941 to advance on narrow fronts at a number of points and surround the Russian forces by pincer movements. But the bulk of the Russian army was able to withdraw into the vast Russian interior and was still in being in 1942. In fact the Russians were able with some success to assume the offensive during the winter 1941-42. In 1942 the Germans changed their strategy, and used their mechanised and armoured forces to advance at a large number of points on a wide front. This caused sufficient confusion to enable normal German formations to advance and occupy areas gained by the armoured forces.

"Second Front" Strategy

In the spring of 1942 the Russians were carrying the main burden of the war. The Germans had a total of 175 divs. on the Russian front and there was a strong demand that the Allies should reopen a front in W. Europe to relieve this pressure. The Germans had less than 30 divs. in France and the Netherlands, and the defensive works called the Atlantic Wall had hardly been started. From a strategic point of view this seemed to be a golden opportunity. But very few landing craft were available; U.S. land forces scarcely existed yet, the

U.K. had only 10 infantry and 5 armoured divs. and 10 army tank bdes. in Great Britain; the Allied air forces had not yet gained superiority over the Germans.

It was decided therefore that no attempt to land in France could be made in 1942, and the Allies were undoubtedly right in not taking this risk under the conditions that existed at that time. But Winston Churchill had never forgotten his desire in the First Great War to find "an easy way round" via the Balkans. This idea was now extended to an attack on Germany from many points in the Mediterranean—an attack on, as he called it, the "soft under-belly of the Axis." The first step was to take the N. African coast, after that to capture Sicily and the toe of Italy.

Mediterranean or English Channel?

The strategy of squeezing out the Germans and Italians by attacking from both ends of the N. African coast proved to be sound. In the meantime Russia had won a winter campaign and had followed this up with success for the first time in a summer campaign in 1943. The Russians had about three times the strength of the Germans on that front. The Allies were making good headway in the submarine war and in gaining naval control in the Atlantic. The choice now lay between attacking Germany across the Channel from England, or from the Mediterranean. The U.S.A. considered that the Allies should turn their efforts to an assault across the Channel at the earliest possible moment after the winter operations in N. Africa had been concluded. The British prime minister and C.I.G.S. were strongly attracted to the plan of attacking Germany from the Mediterranean; and from a purely strategical point of view they were probably correct. A compromise plan was therefore adopted. Forces of limited strength and some landing craft were to be left in the Mediterranean, while the bulk of the Allied forces were concentrated in the U.K. This resulted in a serious dispersion of the Allied forces.

If the U.S. plan of concentrating all available resources at the earliest possible moment in the U.K. had been adopted it would have been possible but risky to launch the offensive in 1943. If the U.S.A. had agreed that all forces should be concentrated in the Mediterranean, final victory might have been secured six months sooner than it was. A

great and vital risk was, however, involved in this plan. The Allies already had considerable knowledge about the German plans for the manufacture of rockets and other reprisal weapons to be installed in the N. of France and in the Netherlands. Had the Allies advanced from the S., the Germans might have been able to wreck the Allied bases in England while they delayed the Allied advance from the S. An advance across the Channel would lead the Allied forces directly on to the areas where these weapons were installed; and this in fact happened, just saving England from great devastation.

D-Day Strategy, and After

Strategical considerations as regards the locality at which the landing was to take place were comparatively simple, but Allied strategy after landing was more difficult. The period during which the Cotentin pen., with Cherbourg, was being captured, and a secure defensive ring extending some 15 to 20 m. inland from the landing beaches was being established, was seen to be the most dangerous. A strong counter-attack during the first 10 days after the landing might have met with success. The Allies, however, had spread false information with skill and success; and the German high command, convinced that the main landing was to be made farther E., refused to allow the withdrawal from elsewhere of the troops needed for such a counter-attack.

As strategy after the landing in Normandy the commanders of the British and U.S. armoured forces favoured advances at a few points on narrow fronts and pressing deep into enemy territory with a view to causing confusion and collapse of the opposing forces. This plan worked until the failure, through insufficiency of aircraft, of the air advance across the Rhine. After that, the Allies had to accept a plan of an advance up to the Rhine on the whole front. There were no special strategical considerations in the final stages of the war in Europe.

As soon as success was assured against Germany, all possible reinforcements in men and munitions were sent to the Far East. A degree of overwhelming strength was built up in that theatre and victory was in sight before the first atomic bomb was used. The great strategic power of comparatively small armoured forces, supplied by air to retain their mobility, was clearly demonstrated

in the Burma campaign. See Tactics; also First Great War; Second Great War.

Stratford. District of Greater London. In the co. of Essex, 4 m. by rly. N.E. of Liverpool Street, its old name was Stratford Langthorne. It is a ward of the bor. of West Ham. The bridge over the Lea, uniting Stratford with Bow (*q.v.*), replaced in 1839 one dating from the 12th century. The buildings include several churches, among them S. John's, 1834, a town hall, 1867-69, technical institute, municipal college, library, baths, and theatre. There are manufactures of chemicals, paint, varnish, and candles; printing works and breweries, and rly. workshops and depot.

A moated Cistercian abbey, founded in 1135, stood in the marshes on Abbey Creek, a branch of the Lea. It was dissolved in 1538.

Stratford de Redcliffe, STRATFORD CANNING, VISCOUNT (1786-1880). British diplomatist.

Viscount Stratford de Redcliffe, British diplomatist
After G. F. Watts

Born in London, Nov. 4, 1786, cousin of George Canning, he was educated at Eton and King's College, Cambridge. He held his first diplomatic appointment at 21, and was minister plenipotentiary at Constantinople in 1810; acting entirely on his own initiative, he negotiated the treaty of Bukarest, 1812. He held important appointments in Vienna, 1815, Washington, 1819, St. Petersburg, 1824, and Constantinople, as ambassador, 1825-28. When not employed in diplomacy, he sat three times in parliament as a moderate Tory.

From 1842 to 1858 he served again as ambassador to the sultan of Turkey, making there the extraordinary reputation so vividly described by Kinglake, which won him the title of the Great Elchi (Turkish for ambassador). Stratford de Redcliffe, who received his peerage in 1852, was an extremely skilful diplomatist and exercised almost boundless influence over the Turks. He must therefore take much responsibility for not averting the Crimean War. In 1856 he persuaded the sultan to grant reforms, including a decree securing rights for the Christians. He retired in 1858, and died at Frant, Aug. 14, 1880.

Stratford-upon-Avon. Mun. bor. and market town of Warwickshire, England. Pleasantly situated on the

Stratford-upon-Avon arms

at the Avon, it is 24 m. S.S.E. of Birmingham by rly. The fine cruciform parish church of Holy Trinity, restored 1891-92, dates principally from the 14th and 15th centuries. It contains the grave and monument of Shakespeare, with a portrait bust, and the grave of his wife, Anne Hathaway. The old guildhall, in which strolling players performed, was restored in 1892. The upper story is occupied by King Edward VI's grammar school, which Shakespeare attended. Before its refoundation it was connected with the Guild of the Holy Cross, the chapel of which still stands. The magnificent bridge of 14 arches which crosses the Avon was built late in the 15th century by Sir Hugh Clopton. A fine old house in the town was the home of the mother of John Harvard (*q.v.*).

The birthplace of Shakespeare in Henley Street was purchased for the nation in 1847 for £3,000, and contains a unique collection of books, pictures, etc., illustrating his life and times. New Place, in which the poet died, was acquired by him in 1597. It was destroyed in 1759, and its site, with a few remains, was purchased by public subscription in 1862, and handed over to the trustees of the birthplace. The new Shakespeare Memorial Theatre (*q.v.*) was opened in 1932. A fine statue of Shakespeare was presented by Lord Ronald Gower in 1888, and a memorial fountain was erected in 1887 by an American, G. W. Childs. In the vicinity Charlecote Park, now National Trust property, Clopton, Luddington, Snitterfield,

Stratford-upon-Avon. Plan of the Warwickshire town intimately associated with Shakespeare

Stratford-upon-Avon, Warwickshire. Left, Shakespeare's birthplace in Henley Street, restored 1857-58. Right, the room in which the poet is said to have been born

and Wilmoote have memories of Shakespeare, and at Shotton is the cottage of Anne Hathaway.

An extensive trade in agricultural produce and cattle is carried on. The corporation supplies gas and water. Market day, Fri. In 691 a monastery was established at Stratford, which received a charter of incorporation in 1553. Pop. 11,616. See Harvard; Hathaway; Shakespeare.

Strath (Gael, open valley, from Lat. *strata*, a road). Name given in Scotland to broad valleys as distinct from glens, e.g. Strathspey and Strathmore (*q.v.*).

Strathaven. Market town of Lanarkshire, Scotland. It stands near the Avon, 16 m. S.S.E. of Glasgow, and is served by rly. Near the town are the ruins of the castle. * Strathaven, also called Avondale, was made a burgh in 1450. Market day, Tues. Population 5,902.

Strathclyde. Ancient British or Welsh kingdom in S.W. Scotland. Also called Cumbria, it included the basin of the Clyde and Ayrshire, and, at an early period, Cumberland. It appears to have been consolidated by Rhydderch Hen about 573. The capital was Dumbarton, anciently called Alcluth. Strathclyde submitted to Northumbria in 756, and to Edward the Elder of England in 925, and passed to Malcolm I of Scotland in 971, but was not fully merged in Scotland until the 11th century.

Strathcona. Town of Alberta, Canada, since 1912 part of Edmonton. Known also as South Edmonton, it stands on the S. bank of the N. Saskatchewan river and is connected with the city by a steel bridge 2,550 ft. long. Here are the buildings of the university of Alberta founded in 1906. Named after Lord Strathcona, the town had a pop. of 6,500 before its absorption by Edmonton (*q.v.*).

Strathcona and Mount Royal, DONALD ALEXANDER SMITH, BARON (1820-1914). A Canadian politician. Born Aug. 6, 1820, at Archiestown, Morayshire, Scotland, he emigrated to Canada when 18 years old. He worked for the Hudson's Bay company, being in Labrador for 13 years, followed by 10 in the Hudson Bay district. In 1868 he was transferred to Montreal, where he became general manager of the Hudson's Bay company in Canada, and eventually governor, an office which he retained to the end of his life.

Lord Strathcona, Canadian politician
Russell

In 1869 open rebellion began in the Red River Territory under Louis Riel. Chosen as special commissioner to visit the rebels at Fort Garry, afterwards he stayed for some time among them, little better than a prisoner, but did much to break down opposition. When British troops arrived, Smith was requested to administer affairs at Red River. He was member of the executive council of the North-West Territories, represented Winnipeg in the Manitoba legislature, and was one of the first representatives of Manitoba in the dominion house of commons.

Realizing the necessity of railway communication with the Pacific, Smith, with his cousin, George Stephen, afterwards Baron Mount Stephen, and others, formed a syndicate to build the Canadian Pacific Railway (*q.v.*). They plunged into the colossal task with great zeal. The construction of the railway was begun in 1881. The last spike was driven in by Smith, Nov. 7, 1885, at Craigellachie in the Rockies

Knighted in 1886, Smith accepted in 1896 the high commissionership for Canada in England. In 1897 he was made a baron of the United Kingdom, with the title of Lord Strathcona and Mount Royal. He continued as high commissioner until his death on Jan. 21, 1914, at the age of 93, working regularly at his office until within a few days of the end. His title descended by special decree to his daughter, Margaret Charlotte Smith (1854-1921), whose son, Donald Sterling Palmer Howard (b. June 14, 1891), became 3rd baron. He occupied various govt. posts, and was captain of the Yeomen of the Guard, 1931-34.

Strathfieldsaye or **STRATFIELD-SAYE.** Parish and village of Hampshire, England. It is 7 m. S.E. of Basingstoke, near the river Loddon, and contains the estate granted by parliament to the first duke of Wellington in 1817. Purchased at a cost of £263,000, it was previously in possession of the earl of Chatham and his son, William Pitt. It is the seat of the present duke of Wellington. The estate is held by virtue of the quit-rent of a silk standard, tendered to the king on the anniversary of the battle of Waterloo, June 18.

Strathmore. Valley of Scotland. In the narrowest sense it consists of a tract of land extending between Brechin, in Angus, and Methven, in Perthshire.

Generally the Great Plain is regarded as comprising the area between the Grampian Mts. on the N. and the Lennox, Ochil, and Sidlaw Hills on the S., with a length of about 100 m. and a breadth averaging 8 m.

Strathmore and Kinghorne, EARL OF. Scottish title held by the Lyon family. Patrick Lyon, 9th Baron Glamis, head of a Scottish family which had held the barony since 1445, was created earl of Kinghorne in 1606. His grandson

Patrick, 3rd earl, was a lord of the treasury, and in 1677 was made earl of Strathmore and Kinghorne. His grandson John, the 5th earl, was killed fighting for the Pretender at Sheriffmuir, 1715, and was succeeded in turn by his three brothers Charles, James, and Thomas. John, 9th earl, son of Thomas, took the additional name of Bowes, and from him the subsequent earls are descended. Patrick Bowes-Lyon, 15th earl (1884-1949) was a brother of Queen Elizabeth. He was succeeded by his son Timothy (b. 1918). The family seat is Glamis Castle (*q.v.*), Angus, and an eldest son bears the courtesy title of Lord Glamis.

Strathpeffer. Village and watering-place of Ross and Cromarty, Scotland. It is 5 m. by rly. W. of Dingwall, and is overlooked by Ben Wyvis, 3,429 ft., from the N. It is noted for its mineral springs, sulphur and chalybeate, and has baths and hotel accommodation. Pop. 875.

Strathspey. Scottish dance said to have originated in the valley (strath) of the Spey. It has been compared with the reel, from which, however, it differs by its more broken movements in dancing, indicated in the music by the prevalence of dotted notes.

Stratification. In geology, formation of rocks into layers. Stratified rocks are usually sedimentary, and when the strata are very thin they are known as laminae. See Geology; Rocks; Sedimentary Rocks; Stratum.

Stratigraphy. In geology, the study of strata, or historical geology. It deals with the time-sequence of geological deposition and events, and the conditions under which the rocks were laid down. The absolute ages of rocks have been established with fair accuracy by measuring the degree of disintegration of radio-active elements contained in them. Most geological time-conceptions are relative, one time period being earlier or later than another, and no quantitative element of time is involved. By considering the sequence of deposition of strata one can state that certain beds are older or younger than those respectively above or below. This is the law of superposition. By examination of the fossil content of these beds the time-sequence of the appearance and disappearance of species has been worked out. The time relationship of igneous rocks to local sediments is shown by the age of the strata penetrated by intrusions or covered by lava

flows. By application of such principles a time succession for the formation of the rocks of the earth's crust has been built up.

The conditions in which rocks were deposited are shown by the characters of the rocks themselves. From observations of sedimentation still going on past conditions can be deduced. By recognition of and tracing deposits of a certain age laid down in varying depths of water, or on some past land surface, it is possible to outline ancient land and sea areas, and by attention to the character of the fossil fauna and flora, etc., to obtain some idea of the climatic conditions prevailing at that distant period. In the geological exploration of coal, oil, water, or other deposits associated with sedimentary rocks a detailed knowledge of stratigraphy is essential. (See Geology; Fossils; Earth Movements; Igneous Rocks; Sedimentary Rocks; consult Introduction to Stratigraphy, L. D. Stamp, 1923).

In archaeology, the stratigraphical method is also used, *e.g.* in certain caves the flint implements of early Palaeolithic men have been found in the lowest strata, sealed by a sterile stratum of detritus accumulated during a long period of abandonment by man. Above such a sterile layer may come strata containing late Palaeolithic flints and, in some cases, yet higher strata containing Neolithic remains. The sequence of the strata enables the archaeologist to determine the relative dates of the different cultures.

Stratosphere. Meteorological term. It was first applied in 1909 by Teisserenc de Bort to describe the external layer of the atmosphere, in which there is no appreciable convection, and which he had discovered 10 years previously. Professor Picard (*q.v.*) ascended to over 53,000 ft. in 1932; two Americans in 1935 reached over 74,000 ft.

The temp. of the air usually decreases with increase of height from the earth's surface, at an average rate of about 10° C. per mile; but eventually a level is reached where the upward decrease ceases. It was at first believed that the temp. of the stratosphere was isothermal, but it was revealed that the temperature is not always the same and may vary horizontally as well as vertically. Indeed, a high proportion of the balloon soundings into the lower stratosphere, made at a number of places on the earth, indicate that there is an increase of temp. with height. The temp.

of the stratosphere also varies with the latitude and the weather, *e.g.* over the poles it is -50° C. (-20° C. at the surface) and over the equator -80° C. (+25° C. at the surface). At the poles the mean rate of decrease of temperature is only about 5° C. per mile, owing to the inversion of temperature near the ground, but the chief reason for the lowest stratospheric temperature occurring over the equator is that the troposphere (*q.v.*) there extends to a greater height. On the average, the lower boundary of the stratosphere—the tropopause—is at a height of 10 m. at the equator compared with 5-6 m. at the poles; in England it may be about 5 m. during the type of weather associated with the passage of depressions and 8 m. in anticyclones.

Whereas the decrease of temp. vertically in the troposphere is due to the continual mixing and interchange of air between different levels, the nature of the temp. distribution in the stratosphere indicates that these processes are very limited. The main control of stratosphere temp. is attributed to radiation, the stratosphere absorbing the energy of sunlight and of the upward stream of low-temperature radiation from the ground and the troposphere, and, in turn, radiating outwards. Analyses of samples of air obtained at heights of up to 15 m. have shown that the change in composition is slight; ozone (*q.v.*) is, however, more plentiful in the stratosphere, the maximum recorded concentration being at about 17 m. The air of the stratosphere is extremely dry, even allowing for the low temperature, and as the driest air should lie over the equator, this is indicative of a general circulation in the stratosphere. With the exception of the beautiful iridescent "mother-of-pearl" clouds which have been seen occasionally after sunset, and located at a height of 14-18 m., the stratosphere is cloudless.

Because of the almost complete absence of cloud and rain, and the low density of the air reducing resistance, the stratosphere is an ideal medium for aircraft, and aeroplanes have been developed to fly in the substratosphere. Both military and civil long-distance aircraft normally fly at sub-stratospheric altitudes.

Stratospheric flight requires a specialised type of fuselage and power unit. Lack of oxygen renders the ordinary internal combustion engine inefficient and

necessitates the use of costly, heavy, and complicated supercharging systems and cooling devices. When the air is compressed by a supercharger it becomes exceptionally hot, and the thin air at great heights does not carry away the heat from the engine as quickly as does the more dense air at lower levels. Propeller traction also is inefficient at stratospheric altitudes, as the thin air does not offer sufficient "body" for the propeller to grip and screw its way forward. The most efficient power unit for high altitude flying in stratospheric conditions is the jet or rocket, which operates through the reaction to a rear discharge and has few moving parts to overheat.

Lack of oxygen in the stratosphere prevents human beings from breathing, and aircraft for stratospheric flight must have sealed pressurised cabins. These cabins are maintained at an interior pressure eight to ten times greater than that obtaining outside. Experiments since the Second Great War have indicated that the speed of rocket-propelled flight in the stratosphere is limited only by the structural strength of fuselage and power unit. *See Meteorology; Radiation; Troposphere.*

Stratton. Market town of Cornwall, England, part of the urban dist. of Stratton and Bude. It is 16 m. N. by W. of Launceston, standing in a valley surrounded by high hills. The station is Bude, 1½ m. On Stamford Hill, just outside the town, a parliamentary army was defeated by the Cornishmen under Sir Bevil Grenville and Sir Ralph Hopton on May 16, 1643. Pop. 3,000.

Stratton, EUGENE (1861-1918). American singer. He was born at Buffalo, N.Y., May 8, 1861, and made his first stage appearance at the age of ten.

Eugene Stratton,
American singer

In 1880 he came to London, and after ten years with the Moore and Burgess Minstrels he was engaged at the Holborn Music Hall, 1892, and thereafter gained great popularity throughout the country with his coon songs, such as the famous Lily of Laguna. He died Sept. 8, 1918.

Stratum OR BED. In geology, name given to a single layer (plural strata) of sedimentary rock.

These rocks were deposited on the bottoms of former seas or lakes, on the surfaces of plains and deserts etc., and the term stratum is very similar to that of seam or layer. One stratum is separated from another by bedding planes, which show an interruption in the process of formation of the strata. *See Geology; Stratigraphy.*

Stratus. Uniform sheet of low cloud, resembling fog but not resting on the ground, and so called because it has the appearance of layers or strata. In the British Isles it usually forms at heights of 500-2,000 ft., tending to disperse during the day in summer and to persist in winter. *See Cloud.*

Straubing. Town of lower Bavaria, Germany. It stands on the right bank of the Danube, 26 m. S.E. of Ratisbon. The chief buildings are the castle, once the residence of the dukes of Bavaria; Straubing, the churches of S. Peter, S. James, and S. Ursula, the Carmelite church, and the town hall which dates from 1382. There is a clock tower 215 ft. high, which was built in 1316. Straubing has associations with Agnes Bernauer, who was drowned here as a witch in 1435. After the Second Great War it came within the American zone of occupation. Pop. 36,000.

Straus, OSCAR (b. 1870). Austrian musician, who in 1939 became a naturalised Frenchman. He was born March 6, 1870, in Vienna. He wrote music for the light operas, *A Waltz Dream* and *The Chocolate Soldier*, performed in London in 1908 and 1910 respectively. From youth until 1900 he was conducting at theatres in Vienna and Berlin, but later he lived in New York and Paris.

Strauss, DAVID FRIEDRICH (1808-74). A German theologian. Born at Ludwigsburg, Jan. 27, 1808, and educated at Tübingen and Berlin under Baur and Schleiermacher, he became a teacher. In 1835 he published his *Life of Jesus*, which was translated into English by George Eliot, and caused a great sensation by its extreme standpoint, from which Christianity was viewed as a myth and Christ simply as a Jewish philosopher. Strauss had been elected to the chair of philosophy at Zürich, but was at once retired, and he then virtually abandoned Christianity altogether. His later published works were largely attacks on Christianity, which he now regarded as a kind of pantheistic combination of Greek and Jewish mythology. He died Feb. 8, 1874.

Strauss, GEORGE RUSSELL. Contemporary British politician. Son of a Conservative M.P., he was educated at Rugby, and joined the Labour party during the 1920s. He was M.P. for N. Lambeth 1929-31 and 1934-50, thereafter for Vauxhall. A close associate of Sir Stafford Cripps, with whom he was expelled from the labour party 1939-44, he was his parliamentary private secretary 1942-45. In 1947 he became minister of supply. On the L.C.C. he represented N. Lambeth 1925-31, and S.E. Southwark 1932-46, and served as chairman of the supplies committee during 1937-39.

Strauss, JOHANN (1804-49). Austrian composer, born in Vienna, March 4, 1804. At 15 he joined a band as violinist, and from 1826 toured his own orchestra throughout Europe. The acknowledged originator of the Viennese waltz, he composed 152, as well as 24 galops, 32 quadrilles, 13 polkas, etc. He died Sept. 25, 1849.

Strauss, JOHANN (1825-99). Austrian composer. Born in Vienna, Oct. 25, 1825, he was the son of Johann Strauss (v.s.) and after an attempt at a business career, turned to music and succeeded his father as conductor of his orchestra.

From 1863 he devoted himself to composition, and outdid his father's fame with such astonishingly successful waltzes as *The Blue Danube*, first performed in 1867. His light operas, full of flowing and rhythmic melodies, included *Indigo*, 1871; *Die Fledermaus*, 1874; *A Night in Venice*, 1883; and *The Gypsy Baron*, 1885. Strauss was the acknowledged master of waltz composition in the Viennese tradition. He wrote over 400 waltzes, as well as polkas, mazurkas, and galops. He died in Vienna, June 3, 1899.

Strauss, RICHARD (1864-1949). German composer. Born June 11, 1864, at Munich, he was educated in music from childhood, and studied aesthetics and philosophy at Munich university, 1882-83. His symphony in D minor was played in 1881, a violin

Richard Strauss,
German composer

concerto in 1883, and his remarkable F minor symphony in 1884 in New York. Assistant conductor to Bulow, 1885, he came under the Wagnerian influence, as his tone poems, Don Juan, 1889, and Death and Transfiguration, 1890, bear witness. Till Eulenspiegel, 1895. Don Quixote, 1898; Ein Heldenleben, 1899; and the Sinfonia Domestica, 1904, represent further developments of the symphonic poem. Strauss turned to opera with Guntram, 1894, and Feuersnot, 1901, and caused a great sensation with more daring operatic experiments in Salome, 1905, and Elektra, 1909. Der Rosenkavalier, 1911, was in lighter vein, but later works were not so successful. He first appeared in London in 1922, and conducted there in 1947. He died at Garmisch, Sept. 8, 1949.

Strauss's orchestration roused much controversy. He not only worked for effects beyond those of Wagner, but added specially made instruments for certain effects. A master of cacophonous scoring, he could nevertheless write melodies worthy of the great masters, as shown especially in his songs; and in spite of his failures is probably the foremost German composer of his generation. *Consult* Richard Strauss, E. Newman, 1908.

Stravinsky, Igor Fedorovich (b. 1882). Russian-born American composer, born at Oranienbaum.

Igor Stravinsky, American composer

June 5, 1882. On Rimsky-Korsakov's advice he abandoned law for music in 1902. His early orchestral music, including Fireworks, attracted the attention of

Diaghilev, by whom he was commissioned to compose for the ballet The Firebird, 1910. Next year was produced his masterpiece Petroushka, unsurpassed in the development of the ballet. Le Sacre du Printemps, 1913, expressed elemental brutality in a manner never before successfully attempted. Later ballets included Pulcinella, 1919; Les Noces, 1923; Le Baiser de la Fée, 1928. He composed operas, The Nightingale, 1914, and Mavra, 1922, and the oratorio Oedipus Rex, 1928. Stravinsky's principle from 1910 to about 1930 was that music should make a purely physical appeal. A master of cacophony and counterpoint, he exploited to the full the possibilities of orches-

tral texture and individual instruments. Then he adopted a severely classical style in such works as Symphonie de Psaumes (for choir and orchestra), 1930; concerto for two pianos, 1935; concerto for 16 instruments (Dumbarton Oaks), 1938; symphony in C, 1943. Stravinsky lived in Paris for many years, but went to the U.S.A. shortly before the Second Great War and became an American citizen in 1945. He published Chronicle of My Life, 1936; The Poetics of Music, 1948. *Consult* Life, E. W. White, 1947.

Straw. Stems of cereals (white straw crops) and also those of pea and bean (black straw crops). The latter is a valuable fodder, more nutritious than cereal straw. By chaffing or steaming pea straw it can be converted into useful fodder for milch cows and ewes.

Cereal straws, especially of wheat, are universally employed as litter, which afterwards has an important mechanical action on the soil as a constituent of manure. Straw is valuable as a fodder in the case of cattle and other ruminants, not only on account of the nutritious substances it contains, but also because the comparatively indigestible fibre gives the necessary bulk required to fill the large paunches of these animals. Another important use of cereal straw on the farm is for thatching (*q.v.*). It is further used for packing, stuffing mattresses, making certain kinds of paper and cardboard (see Strawboard), and for straw-plaiting. Wheat straw is used in the last-named industry, the crop being pulled, not cut, and the ears removed by hand, after which the straw is stripped, cut up, sorted into different sizes, and tied into bundles. *See* Fodder; Hat; Litter.

Strawberry (*Fragaria*). Genus of perennial herbs of the family Rosaceae. The leaf is a trefoil, rough and toothed, hairy upon the underside; the white or yellow five-petalled flowers are unisexual. The edible fruits consist of a fleshy receptacle, with numerous achenes embedded on the surface. Of the ten species, *F. vesca* is a native of Great Britain, and, but for its smaller size, is similar to the cultivated varieties. The chief garden varieties have been derived from the wild strawberry, the Virginian (*F. virginiana*), the Chilean (*F. chilensis*), and the haitbois (*F. elatior*).

The strawberry propagates itself by means of fast-growing runners. Roots should be planted in autumn or spring, in a deep,

well-drained loam, free from clay, and on a S. slope, if it is intended to grow the fruit in large quantities. The plants should be established in rows 2 ft. or 2 ft. 6 ins. apart, with a space of 12 ins. between each plant. In spring the beds should have a mulch of manure, and later a layer of straw should

Strawberry. The edible fruit in different stages of growth

be spread about the roots of the plants. This precaution is to prevent heavy rains from causing the surface soil to splash up and damage the fruit during formation and development.

All runners should be removed from the plants and pegged on to the surface of the bed, to be potted up in Aug. or Sept. when rooted. By potting up runners of early and late sorts, and by the judicious use of glass protection at varying temperatures, it is possible to obtain strawberries all the year round, although the out-of-season fruit lacks flavour and often colour. In addition to propagation by runners, strawberries may be increased from seed sown in boxes in the greenhouse in spring. Strawberry plants should be renewed every three years to obtain the best results. *See* Fruit.

Strawberry Hill. London suburb. It is between Twickenham and Hampton, in Middlesex. The district, which has a rly. station, takes its name from the villa built in 1747 by Horace Walpole, originally a cottage overlooking the Thames. Walpole purchased it from a Mrs. Chevonix and built a little false-Gothic stucco castle, where he lived for the remainder of his life, amassing a wonderful collection of pictures and curios which was dispersed at the Waldegrave sale in 1842. *See* Walpole, Horace.

Strawberry Tree (*Arbutus unedo*). Small evergreen tree of the family Ericaceae, a native of the Mediterranean region and Ireland. It attains a height of

only 10 or 12 ft., and has red-tinged, scaly bark. The alternate oval leathery leaves have toothed

Strawberry Tree. Twigs bearing foliage, flowers (top), and fruit

edges, and the creamy, bell-shaped flowers droop in clusters. The fruit is a round orange-red berry, whose entire surface is raised into little points. It takes over a year to develop fully and ripen, when it is edible but not very desirable, except as a preserve. See *Arbutus*.

Strawboard. Type of cardboard. Made from crude straw pulp, usually in sheets 30 ins. by 25 ins., it is used for cheap bookbinding and for mounting photographs.

Straw Plaiting. Industry preparatory to the manufacture of straw hats. It was originally carried on in Italy. The best straw for this purpose is grown in Tuscany, being that of a special kind of wheat. Before the wheat is ripe the plant is pulled up, and the straw is dried and submitted to other processes before it is ready for the plaiters. Soon after 1600 straw plaiting was introduced into England, and in Bucks and the adjacent counties straw was grown for the purpose, being then cut, selected, and prepared. The plaiting gave employment to thousands of women, and the hats were made at Luton and elsewhere, but towards the end of the 19th century the import of plaits from Japan and Italy almost destroyed the industry in England.

Streamlining. Popular name for a method of design of aircraft, motor vehicles, rly. engines, intended to reduce their resistance to the air during movement. It is dependent on a study of the dynamics of gases, particularly as related to the influence of forces acting on bodies in motion in the air. See *Aerodynamics*; *Fairing*; *Head Resistance*.

Streatham. Residential suburb in S. London. In the met.

bor. of Wandsworth, it is about 6 m. from the City, with which it is connected by trams, buses, Green Line services, and three rly. lines. It comprises Streatham proper, where are remains of the old village, and the more modern Streatham Hill. S. Leonard's is the chief of several churches. Streatham Common is a fine open space covering about 60 acres. Connected with it are the grounds of the Rookery, now public property. Streatham has associations with Johnson and the Thrales. Streatham is a bor. constituency of Wandsworth. Pop. 68,435.

Street. Urban dist. of Somerset, England. It may be reached by rly. and is 14 m. E. of Bridgwater. There are tanneries, vehicle works, leather board mills, and manufactures of footwear. Pop. 5,000.

Street, ARTHUR GEORGE (b. 1892). British farmer and writer. Born April 7, 1892, at Ditchampton

A. G. Street, British writer

farm, near Salisbury, he succeeded to the ownership on the death of his father in 1917. Educated at Dautsey's school, Devizes, he was farming in Manitoba before the First Great War. Of some 20 country studies and partly autobiographical volumes, the first and best known was *Farmer's Glory*, 1932; *Country Calendar* appeared in 1935, *A Year of My Life* in 1939, *Ditchampton Farm* in 1946. Street was also a broadcaster and lecturer.

Street, GEORGE SLYTHE (1867-1936). British writer. Born July 18, 1867, at Wimbledon, and educated at the Charterhouse and Exeter College, Oxford, he was one of W. E. Henley's disciples and wrote essays and other works distinguished by observation, characterisation, and dramatic instinct. The essays include *Miniatures and Moods*, 1893; the satires, *The Autobiography of a Boy*, 1894; the novels, also satirical, *The Wise and The Wayward*, 1897, and *The Trials of the Bantocks*, 1900. He also wrote *The Ghosts of Piccadilly*, 1907; *At Home in the War*, 1918. In 1914 Street became joint examiner of plays, and in 1920 reader of plays. He died Oct. 31, 1936.

Streicher, JULIUS (1885-1946). German Nazi politician. He was born Feb. 12, 1885, at Fleinshausen. Soon after the First Great War, in which he fought with distinction, he was

dismissed from his post as a teacher at Nuremberg for a penal offence. In 1921 he founded the violently anti-Semitic group called Germanic Socialists, soon merged with the Nazi party; he took part in Hitler's *putsch* of 1923 and was imprisoned with him. Released, Streicher started in 1924 *Der Stürmer*, a pornographic anti-Jewish weekly. Member of the Bavarian diet and of the Reichstag from 1932, he was appointed Gauleiter of Franconia as soon as Hitler assumed power. He made a huge fortune from his paper, advocating the most brutal exploitation of power. One of the major war criminals indicted at the Nuremberg trials, he died Oct. 16, 1946, at the hands of the hangman.

Julius Streicher, German politician

Streit, CLARENCE KIRSHMAN (b. 1896). American political theorist, the leading advocate of federal union. Born Jan. 21, 1896, he was educated at Montana university and the Sorbonne. After serving in the First Great War he became a journalist, and was Geneva correspondent to the *New York Times*, 1929-38. His much discussed book, *Union Now*, 1938, proposed that a nucleus of the leading democracies should form a federal union designed to merge into the united states of the world. Local committees established throughout the U.S.A. led to the foundation of Federal Union, Inc., of which Streit became president. *Union Now with Britain*, published 1941, proposed this move as a first step.

Strength Through Joy (Ger. *Kraft durch Freude*). Nazi social organization. Copied from the Italian Fascist *Dopolavoro* (literally, after work), and started in 1933 as a branch of the German labour front under Dr. Ley, it was intended to appeal to the whole working population by providing free or at nominal fees spare time musical, theatrical, sporting, and other entertainments. Its main success was with arranged tours and holidays. By 1937 nine million people were enjoying week-end or longer holiday trips, for which ships were specially built or chartered, huge camps and seaside resorts created, and walking expeditions organized.

Strepsiptera OR **STYLOPS** (Gr. *strepsis*, twisting; *pteron*, wing). Name given to a small group of

minute insects whose larvae and adult females live as parasites within the bodies of bees, wasps, and other insects. The females are maggot-like, while the males are active creatures resembling small beetles. About 16 species are British. The name *Stylops* is that of one of the typical kinds.

Streptococcus. Germ named after the Greek word (*streptos*) for a necklace, because under the microscope its appearance is like that of a string of beads. This micro-organism has many varieties and is the cause of erysipelas, septicaemia, and dangerous inflammatory conditions. Penicillin and the sulphagroup of drugs are normally antagonistic to it.

Streptomycin. Antibiotic drug originated in the U.S.A., and obtained from certain strains of the soil mould *Streptomyces griseus*. When first used streptomycin produced dangerous side-effects due to certain toxic properties; an antidote for these has been found. The drug is prescribed for some tuberculous infections. An improved form was called neomycin. See Penicillin.

Stresa. Village in the Novara prov. of Piedmont, Italy. Situated by the W. shore of Lake Maggiore, it is on the Simplon rly. and 75 m. N.E. of Turin. It has fine scenery and is a holiday resort. Stresa gives its name to a conference held here between 15 European powers in 1932 on the initiative of Mussolini to discuss financial and economic problems of central and eastern Europe and control of the Danube basin. On major issues Italy sided with the western powers against Germany.

Stresemann, GUSTAV (1878-1929). German statesman. Born in Berlin, May 10, 1878, of modest parentage, Stresemann secured a university education, a doctor's degree, and in 1902 the secretaryship of an industrial organization at Dresden. Elected to the Reichstag as a Liberal in 1907, he led that then important party from 1917, reconstructing it in opposition to the Left-wing majority. At the crisis of the Ruhr occupation and the inflation of 1923, he was called upon nearly unanimously to form a coalition cabinet.

Chancellor and foreign minister from Aug. to Dec., when the Socialists left the ministry, Stresemann

stayed as foreign minister and was the outstanding figure in all German govts. until his death, Oct. 3, 1929. The Locarno treaty (*q.v.*) of 1925 and cooperation with Briand and Sir Austen Chamberlain inaugurated a systematic attempt at European unification, based upon economic needs and reciprocal interests. Stresemann effected the entry of Germany into the League of Nations. He was awarded the Nobel peace prize in 1926 jointly with Briand. Much attacked by Right-wing elements, and suffering from kidney disease, he spent his energy, oratorical power, and gifts as a writer unsparingly, in parliament, and at Geneva, London, Paris, and The Hague. *Consult* Life, A. Vallen-tin, 1931: Diaries, Letters, and Papers, ed. E. Sutton, 1935.

Stretcher. Appliance for carrying helpless persons. It usually consists of two poles, each about 8 ft. in length, between which is stretched canvas some 6 ft. long and 2 ft. wide. One foot is thus left at each end of the poles to serve as handles. Short legs keep the stretcher from the ground. See Ambulance; First Aid.

Stretford. Borough of Lancashire, England. Until the charter of incorporation was granted in 1933, it was a S.W. district of Manchester. Within the borough are four rly. stations, Trafford Park industrial estate, and the Lancashire county cricket ground, Old Trafford. Numerous heavy and light industries cover a range of mechanical construction and food processing. Pop. est. 61,000.

Stretton, HESBA. Pen-name adopted by Sarah Smith (1832-1911), British writer. Born July 27, 1832, at Wellington, Salop, she was a constant contributor to Household Words and All the Year Round. Her first book, *Jessica's First Prayer*, 1867, was translated into nearly every European language. Her other works include *The Doctor's Dilemma*, 1872; *Through a Needle's Eye*, 1879; *Her Only Son*, 1887. She helped to found the London Society for the Prevention of Cruelty to Children. She died Oct. 8, 1911.

Striation (Lat *stria*, groove). In geology, the cutting of grooves or scratches on a rock surface by the passage over it of a glacier, containing boulders picked up by the ice. The direction of striation shows that in which the ice was originally moving. See Glacier; Ice Age.

Strickland, AGNES (1796-1874). British historian. Born in London, August 19, 1796, and educated at home, after her father's death in

1818 she took up writing for a livelihood. Her most successful work was the *Lives of the Queens of England, 1840-48*, written in collaboration with her sister Elizabeth, as were *Lives of the Queens of Scotland and English Princesses, 1850-59*; *Seven Bishops, 1866*; and *Tudor Princesses, 1868*; though all were published in her name alone. She died at Southwold, Suffolk, July 13, 1874.

Strickland, GERALD STRICKLAND, 1ST BARON (1861-1940). British administrator. Born May 24, 1861, he was educated at Oscott and Trinity College, Cambridge, and became a barrister. In 1889 he was appointed chief secretary to the Maltese government. He was successively governor of the Leeward Islands, 1902; Tasmania, 1904; W. Australia, 1909-13; New South Wales, 1912-17. He went back to Malta in charge of the ministry of justice, 1927-32, his tenure of office being marked by bitter controversy with the R.C. Church. An unsuccessful attempt was made on his life. Strickland represented Lancaster as Conservative M.P. from 1924 to 1928, when he was raised to the peerage. Proprietor of *The Times* of Malta, he wrote on the constitution and history of the island. He died Aug. 22, 1940. His daughter, Mabel E. Strickland, editor of *The Times* of Malta, contributed the article in this work on Malta in the Second Great War.

Stricture. Abnormal narrowing of a natural passage in the body, such as the gullet, intestine, or urethra, so as to cause obstruction. The most common causes are inflammation, *e.g.* inflammatory stricture of the gullet after the swallowing of corrosive poisons, and new growths, *e.g.* cancer. When the word is used without further limitation, stricture of the urethra is meant. This common disorder is most often due to gonorrhoea, and may lead to inflammation of the bladder and other serious complications. The condition is generally treated by the passage of instruments known as sounds, of successively larger size, so as to dilate the constricted part.

Strike. Term for the withdrawal of their labour by a group of workers. The word was first used in print in this sense in the Annual Register of 1768 in reference to hatters having struck for a rise in wages, and appears to derive from the sailors' term striking the mast, which brings the movement of the ship to a stop. The complementary action of an employer

Gustav Stresemann,
German statesman

of refusing to allow his men to work is called a lockout.

The object of most strikes has been to secure wages increases and/or recognition of a trade union and of the right to collective bargaining. Notable strikes in the U.K. were that of 672 match girls in E. London, 1888, which secured some amelioration by their employers of the harsh conditions of their labour; the successful E. London dockers' strike, 1889, for a wage of 6d. an hour (the "dockers' tanner"), in which Ben Tillet, Tom Mann, and John Burns came to the fore; the miners' strike, 1912, involving nearly a million men, for a national minimum daily wage, which failed in its object but led to legislation establishing district minima; the railwaymen's strike, 1919, against a threatened wage reduction; the General Strike (*q.v.*), 1926.

By the 20th century the right to organize in trade unions, and to collective bargaining, had been generally recognized in the U.K. The Conciliation Act, 1896, empowered the board of trade to inquire into the causes and circumstances of a dispute, and to take steps towards bringing the parties together by appointing a conciliator or board of conciliation, and to appoint an arbitrator. These powers were subsequently transferred to the ministry of Labour, which has an industrial relations dept., one of whose functions is conciliation.

During both Great Wars arbitration was made compulsory. The Industrial Courts Act, 1919, established a permanent and independent tribunal to consider trade disputes submitted to it. Its decisions are not enforceable, but when a decision is accepted it becomes a part of the contract of employment. The Act empowered the minister to establish a court of inquiry to ascertain judicially the facts of a major dispute, and to report to parliament. See Trade Disputes Acts.

Strindberg, AUGUST (1849–1912). Swedish author. Born Jan. 22, 1849, at Stockholm, the son of a small tradesman, he studied at Uppsala and became teacher in an elementary school in Stockholm, afterwards turning to journalism and the drama. His first play, *Master Olof*, 1872, was unsuccessful. He obtained a post in the royal library at Stockholm, and wrote his first novel, *The Red Room*, 1879.

Strindberg spent the greater part of the next three years in

Paris, Switzerland, and Germany, where he met Nietzsche. His first two novels, bitterly satirical at the

August Strindberg,
Swedish author

expense of Stockholm society, had made him very unpopular among his own people; his volume of cynical stories of married life, *Marriages*, 1884, was held to be an outrage on the Christian religion, and in 1885 Strindberg returned to defend himself in court against his accusers. His trial resulted in an acquittal. In 1885 he published *Real Utopias*. Two of his best works of fiction, *The People of Hemsö* and *The Life of the Skerry Men*, masterly pictures of Swedish life, followed, 1887–88. In 1887 he wrote the play *The Father*, in which his bitterness against women finds expression.

In *Confessions of a Fool*, 1893, translated into English by Ellie Schleussner, he tells the story of his first unhappy marriage, dissolved in 1891. His second marriage brought about a mental crisis which led to his being placed for a time in a sanatorium. His *Inferno*, 1897, a strange study in abnormal psychology, throws much light on his state of mind during this period. The ten years 1898–1908 were very fruitful, producing—in addition to novels, volumes of autobiography, and scientific treatises—no fewer than 29 dramatic works; some of them, such as *Gustavus Vasa*, historical. Others, such as *Christmas*, full of symbolism and mysticism. He died May 14, 1912. Many of his books were trans. into English. *Consult Lives*, L. Lind-af-Hageby, 1913. G. A. Campbell, 1933. E. Sprigge, 1948.

String (*A.S. streng*). Fine, twisted cord for tying parcels, etc. It is made of several strands of hemp, flax, or cotton tightly twisted, wound into balls, and sold by weight. The word is often used to denote anything which forms a line, as a string of cattle, of beads, or a thread upon which a series of things is filed or hung. In music the strings of such instruments as pianos, harps, violins, etc., are made of wire, steel, brass, or catgut—plain or coated with silver.

String Course. In architecture, a horizontal course of brick or stone carried along the face of a building and round angular projections, so as to bind together the

detached portions of an irregular design.

Stripe. In military usage, a mark of rank for the three lowest grades of non-commissioned officers in the British army. See *Chevron*; *Rank*; *Sergeant*, etc.

Stroboscopic Effect. Optical phenomenon. If a body rotating with uniform angular velocity is viewed with intermittent illumination, and the cyclic frequencies are the same or are small multiples of each other, a given point on the body being viewed will appear stationary. This effect is made use of in industry for examining machinery in motion, the source of illumination being adjusted until the moving part appears at rest. The device utilising this effect is known as a stroboscope.

Stroke. Popular term for sudden onset of paralysis and other symptoms due to haemorrhage into the brain substance, or to a clot blocking the blood-supply. See *Apoplexy*.

Stromatopora (Gr. *stroma*, covering; *poros*, pore). Extinct genus of hydroid corals. They formed large coral reefs in Palaeozoic times, and remains are found in various localities in the U.S.A.

Stromboli. Volcano of the Mediterranean Sea. It rises to 3,040 ft. on the north-easternmost of the Lipari Islands, Italy, and is frequently designated the Lighthouse of the Mediterranean. It is continuously active, throwing out lava and "bombs" at intervals of 20 mins. to an hour. Hence the type of eruption known as strombolian. In August, 1907, and June, 1921, it erupted with some violence. The island has a pop. of 2,600, and an area of 5 sq. m. See *Volcano*.

Stromness. Police burgh, market town, and seaport of the Orkney Islands, Scotland. It stands on the S.W. of Pomona, 14 m. W. of Kirkwall, is a summer resort, and has a natural harbour accessible to the largest vessels. Market day, Wed. Pop. 1,692.

Strong, LEONARD ALFRED GEORGE (b. 1896). British writer. Of mixed Irish and West-country parentage, he went from Brighton College to Wadham College, Oxford. At first a teacher, he attracted attention by his verse, but his first novel, *Dewey Rides*,

L. A. G. Strong,
British writer

1926, brought general recognition. This was set on Dartmoor, but in later books, notably *The Garden*, 1931, and *Sea Wall*, 1933, Strong turned to the environs of Dublin for a setting. *The Brothers*, 1932, a story of the Hebrides, was the basis of a successful film, 1947. In 1945 a collection of his short stories, *Travellers*, was awarded the James Tait Black memorial prize. He also wrote criticism, and lives of Thomas Moore, 1937, and John McCormack, 1941.

Strongbow. Nickname of Richard de Clare, 2nd earl of Pembroke (d. 1176). In 1170 he went to Ireland, and, after subduing Waterford and Dublin, married Eva, daughter of the king of Leinster, succeeding to the kingdom in 1171. Strongbow allayed Henry II's jealousy of his successes by surrendering his conquests to the king, but for his services in the Normandy campaign of 1173, Wexford, Waterford, and Dublin were restored to him. Strongbow died at Dublin and was buried in the cathedral.

Strong Room. Fire- and burglar-proof room specially built for the safe custody of valuables. Such rooms commonly form part of a bank's premises, and are available for use by customers, who may deposit boxes containing jewelry, plate, securities, etc. The walls, floor, and ceiling are of ordinary or reinforced concrete, while the door is proof against fire and against attack by thieves. Strong rooms under constant guard are provided by safe-deposit companies for customers who rent them. *See Bank*; *Safe*.

Stronsay. One of the Orkney Islands, Scotland. It lies about 8 m. N.E. of Pomona, has an extreme length and breadth of $7\frac{1}{2}$ m. by $4\frac{1}{2}$ m., covers an area of 14 sq. m., and rises to 155 ft. Its coast is very irregular, the island consisting of three main peninsulas. The parish of Stronsay includes several adjacent islets.

Strontianite. Strontium carbonate, SrCO_3 . It occurs as orthorhombic acicular crystals, fibrous or granular, in colour variable from pale green and yellow to white; transparent to translucent. Strontianite is a source of strontium salts, and the chief commercial deposits are veins traversing Cretaceous marls and limestones in Westphalia, Germany; it also occurs in veins with galena, barytes, etc., and as nodules in limestones.

Strontium. One of the metallic elements. Its chemical symbol is

Sr, atomic number 38; atomic weight 87.63; density 2.54 gm per c.c., melting point 771°C ., boiling point $1,366^\circ\text{C}$. Strontium, one of the calcium group, is a hard yellowish metal, malleable and ductile, and oxidises easily on exposure to the air. It burns with a brilliant crimson flame, a characteristic colour of all strontium compounds when burning. It was discovered by Davy in 1808, and was so named from Strontian, Argyllshire, where the carbonate had been found by Crawford in 1790. It occurs in mineral form in celestine and strontianite, and in small quantities in a few other minerals. It can be prepared by the electrolysis of the fused chloride.

Strontium forms two oxides, the monoxide SrO and the dioxide SrO_2 . The hydroxide is used in the beet-sugar industry for the separation of sugar from beetroot molasses. Strontium nitrate is the substance which gives the red fire in fireworks. In medicine, the bromide, iodide, salicylate, and lactate are used for diabetes, Bright's disease, and rheumatism.

Strood. District of Rochester, Kent. The two parishes, Strood intra and Strood extra, stand on the left bank of the Medway, opposite Rochester proper. The district is served by rly. Pop. 9,463. *See Rochester*.

Strophanthin. Active principle, found useful as a heart tonic, of the seed of *Strophanthus Kembé*, a climbing shrub, native to tropical Africa. From the silky seed cast of this plant the natives produce a deadly poison for their arrow tips.

Strophe. In Greek chorus and dance, the part of a choral ode sung as the chorus passed from right to left, that sung on the return being the antistrophe (*q.v.*). *See Ode*. *Pron.* strofée.

Stroud. Market town and urban dist. of Gloucestershire, England. It stands at a point where several steep, narrow valleys on the W. fringe of the Cotswolds meet before opening into the Severn Vale, and is 12 m. S. of Gloucester by rly. A centre of woollen manufacture, Stroud has a number of cloth mills; it is noted for scarlet dyes, for which the water of the Frome is very suitable. The town has also sawmills, breweries, and iron foundries, and makes fibre board and plastics. Stroud has been connected with the cloth trade since the 16th century. During 1832-85 two M.P.s were elected, it is now in the co. constituency of Stroud and Thornbury. Market day, Fri. Pop. 15,880.

Stroud Green. Residential suburb of N. London. In the bor. of Hornsey, Middlesex, $3\frac{1}{4}$ m. N. of King's Cross, it occupies high ground between Highgate and Finsbury Park. Pop. 9,561.

Strube, SIDNEY (b. 1891). British cartoonist. Born in London, Sept. 30, 1891, he was apprenticed to a furnishing designer, and after studying at Hassall's art school, became a free-lance black-and-white artist. Joining the *Daily Express*, 1912, he became its chief cartoonist, until 1948. His "little man" became a widely quoted symbol of the British citizen. During 1927-41 he published annual books of cartoons.

Strube's "Little Man"

Struensee, JOHANN FRIEDRICH, COUNT (1737-72). German adventurer and Danish statesman. Born at Halle, Saxony, Aug. 5, 1737, the son of a clergyman there, he practised medicine at Altona, and in 1768 became private physician to the weak Christian VII of Denmark, with whom he established himself as a favourite. In 1771 he became minister of state and virtually dictator of a country the language of which he could not speak. He employed his power in enforcing reforms, the encouragement of education, the freeing of the press, trade, and industry. His revolutionary policy and his supposed liaison with the young queen Caroline Matilda, sister of George III of England, roused the nobles and clergy, who arrested him in Jan., 1772, tried him for the intrigue with the queen and for conspiracy against the throne, and had him executed on April 28.

Struma or KARA SU. River of the Balkans. Rising about 20 m. S. of Sofia, in Bulgaria, it flows generally S. through that country into E. Macedonia, Greece, and falls into the Gulf of Orfani, or Contessa, Aegean Sea. Its length is about 150 m.

Strut. Structural member to resist compression in the direction of its length, and to prevent bending actions induced by such compression. Struts are usually slender in section, and the permissible stress in them varies with their slenderness ratio. Typical struts used in building are those for

taking the strain on unframed timber roofs, and the struts of king and queen post roof-trusses. Pillars, columns, stanchions, and posts are forms of strut. The walls and roofs of timbered shafts and galleries in mines are supported by struts.

Various types of strut are used on aircraft. Biplanes have them between the wings, and certain monoplanes are strutted between wing and fuselage. With the development of the thick internally-supported wing, external strutting is now seldom used as it increases wind resistance. Dry docks subjected to high tides or strong wave action are equipped with auxiliary strut gates, consisting of hinged and framed shoring housed at the back of the gate recess, which can be swung into position at the rear of the impounding gates.

Strutt, JEDEDIAH (1726-97). British inventor. The son of a farmer, he was born at Blackwell, Derbyshire, July 28, 1726. He was apprenticed to a wheelwright, where his ingenuity in mechanical matters had scope, but he became a farmer. About 1755, with his brother-in-law, William Woollatt, he invented a machine by which ribbed hosiery could be produced. They started in business in Derby and were successful. Strutt was next associated with Arkwright in spinning cotton, in which other of his inventions were utilised, and the firm they founded had mills at Nottingham, Belper, and Cromford. He amassed a large fortune before he died at Derby, May 6, 1797. One of his descendants was Lord Rayleigh (*q.v.*).

Struve. Name of a family of German astronomers. Friedrich Georg Wilhelm von Struve (1793-1864) was the most important. Born at Altona, April 15, 1793, and educated at Dorpat (now Tartu) university, he was appointed an astronomer there in 1813, and became in 1839 the director of the newly built observatory at Pulkova, near St. Petersburg (Leningrad). There Struve carried out a series of remarkable observations and researches on double and multiple stars. He measured several thousand new star doubles, and his catalogues have proved of great value in checking new discoveries. He died at St. Petersburg, Nov. 23, 1864.

Otto Wilhelm von Struve (1819-1905), son of Friedrich, was born at Dorpat, May 7, 1819, and assisted his father in double star observations. On graduating he

was appointed assistant at Pulkova, where his work was in fundamental astronomy, geodesy, and double stars. In 1862 he succeeded his father as director. He retired in 1889 on the 50th anniversary of the foundation of the observatory, and died at Karlsruhe, Jan. 14, 1905.

Karl Hermann Struve (1854-1920), son of Otto, was born at Pulkova, Oct. 3, 1854, and educated at Viborg and Dorpat, continuing his studies in Paris and Berlin. In 1883 he joined the staff of Pulkova observatory, where he made exhaustive observations of the satellites of Saturn, Neptune, and Mars. Director of Königsberg observatory from 1895, nine years later he took charge of that of Berlin, which in 1913 he transferred to Babelsberg. He died Aug. 12, 1920.

Otto Struve (b. 1897), nephew of the above, was born at Kharkov, Aug. 12, 1897. Educated at Russian universities, he emigrated to America after the revolution and in 1921 was appointed assistant at Chicago university. Instructor at Yerkes observatory from 1924, he became director in 1932. He inaugurated the McDonald observatory in Texas and held its directorship till 1947. Work on interstellar matter, stellar rotation, and the spectroscopy of the stars and nebulae won him the gold medal of the Royal Astronomical Society in 1944.

Strychnine. Alkaloid prepared from the seeds of *Strychnos nux-vomica* and other species of *Strychnos*. It is a white, inodorous, crystalline powder, almost insoluble in water, with an intensely bitter taste. Strychnine and its derivatives are used in medicine as a stomachic and carminative, to stimulate the flow of gastric juices, and to strengthen the muscles of the intestinal tract. Strychnine is a valuable cardiac stimulant, also a respiratory stimulant, and may be given in cases of bronchitis or pneumonia where the respiration is becoming weak. The alkaloid is an exceedingly poisonous drug.

When a poisonous dose of strychnine is swallowed, an intensely bitter taste is perceived. The person soon becomes restless and apprehensive, and has feelings of impending suffocation. These symptoms are rapidly followed by twitching of the muscles and jerking of the head, passing on to general convulsions, often of great violence. The hands are clenched, the limbs thrown out, the head jerked back, and the whole body

becomes stiff. Convulsions recur, and are followed by relaxation. Periods of remission become gradually shorter until convulsions are almost continuous. The contraction of the muscles of the chest prevents breathing, and ultimately the patient dies.

TREATMENT. If a physician is not at hand, an emetic should be given at once, though sometimes this is not possible if the convulsions have already started. When medical aid has been obtained, the patient should be put under chloroform. The stomach is then washed out with potassium permanganate. Large doses of potassium bromide and chloral hydrate should be administered *per rectum*. Chloroform should be continued as long as there is any tendency towards convulsions. During the remissions between spasms, the patient should be allowed to lie absolutely quiet, as the smallest stimulus, *e.g.* a movement, a noise, or a bright light, is sufficient to start the convulsions. *See Drug*.

Strypa. River of Galicia. Until the First Great War it was in Austrian territory; then it became Polish; and as a result of the Russo-Polish treaty of 1945 after the Second Great War was incorporated in the Ukraine S.S.R. It rises E. of Lvov and flows generally S. to join the Dniester below Bucacz. Battles were fought on its banks between Russians and Austro-Germans in 1915.

Strzelecki, SIR PAUL EDMUND (1796-1873). Anglo-Polish explorer. Of aristocratic birth, he came from Prussian Poland, and was educated in Edinburgh. In 1834 he travelled in the Far East. Visiting Australia in 1839 he explored the unknown interior of New South Wales, completing a survey of the Darling Range and discovering Mt. Kosciusko. In the Wellington district he found gold, but at the urgent request of George Gipps, the governor of N.S.W., who feared the effect of such a discovery on the local pop., he kept his find a secret. Back in England from 1843, he published accounts of his discoveries; became a naturalised British subject in 1850, was knighted 1869, and died Oct. 6, 1873. His name is commemorated in some hills in Victoria, a creek in S. Australia, and by several species among Australian flora and fauna.

Stuart. Alternative spelling of Stewart (*q.v.*), the surname of the later Scottish kings. *See* Charles I.; Charles Edward; James I.; Mary Queen of Scots.

Stuart, LADY ARABELLA (1575-1615). English noblewoman. Daughter of Charles Stuart, earl of Lennox, who

was grandson of Margaret, sister of Henry VIII. Arabella stood next in the succession to James when Elizabeth died. Kept a prisoner at Hardwick, she was made the figurehead

Lady Arabella Stuart,
English princess
After van Somer

of a conspiracy in 1603. She married secretly, 1610, William Seymour, afterwards duke of Somerset (*q.v.*), and with her husband was arrested by James I. Both escaped, but Arabella was retaken near Calais and imprisoned in the Tower, 1611, where she died insane, Sept. 25, 1615. *Consult* Life and Letters, E. T. Bradley, 1889.

Stuart, LESLIE (1866-1928). British composer. Born at Southampton, March 15, 1866, he was educated there, and at 15 was organist at S. John's R.C. cathedral, Manchester. He wrote some of the best light popular music of his day: *Soldiers of the Queen*, Louisiana Lou, *Lily of Laguna*. Of his musical comedies the most famous was *Florodora* (*q.v.*), 1899; others were *The Schoolgirl*, 1903; *The Belle of Mayfair*, 1906. He died March 27, 1928.

Stuart Highway. Strategic road of Northern Territory, Australia, constructed during the Second Great War to link the rly. terminus of Alice Springs with that at Birdum, 621 m. to the N. and 316 m. by rly. to Darwin. The road follows the line of the telegraph as shown in the Australia map facing p. 785.

Stubbs, GEORGE (1724-1806). British painter. Born at Liverpool, Aug. 24, 1724, he studied anatomy and became a lecturer at York hospital. He applied his anatomical knowledge to art, and in 1786 published a monumental work on *The Anatomy of the Horse*, with plates drawn and engraved by himself. Elected A.R.A. in 1780, he died in London July 10, 1806. He was one of the greatest sporting painters, and his works can be seen in the National Gallery and the Victoria and Albert Museum.

Stubbs, WILLIAM (1825-1901). British historian and prelate. Born at Knaresborough, June 21, 1825, and educated at Ripon grammar school and Christ Church, Oxford, he was vicar of Navestock,

Essex, 1850-1866. Returning to Oxford as regius professor of modern history, he remained there until 1884, when he was made bishop of Chester. Five years later he was translated to Oxford, where he died, April 22, 1901.

Stubbs's great book, his *Constitutional History of England*, appeared in three volumes during

1875-78. It takes the story down to 1485, and is one of the most solid achievements that stand to the credit of British scholarship. He also selected and edited a volume of *Select Charters*, which, like the

Constitutional History, has passed through many editions. His ripe scholarship is at its best, perhaps, in the Introductions he wrote to 19 volumes of English chronicles published in the *Rolls Series*. *Consult* Letters, W. H. Hutton, 1904.

Stucco. Cement or plaster used as a facing material on the outside or inside surface of walls, or for the decorative treatment of ceilings. A stucco extensively used by the brothers Adam consisted of about equal parts by weight of stone lime and finely powdered bone ash, with about four times their combined weight of clean sand. *See* Building; Cement; Plaster.

Student Christian Movement. Fellowship founded 1889 of students desirous of understanding the Christian faith and living the Christian life. It is interdenominational and international, and is affiliated to the World Student Christian Federation. It has offices at Annandale, North End Road, London, N.W.11.

Stud Farm. Establishment on which blood-stock, i.e. thoroughbred racing stock, is reared. The breeding of racehorses, now a very considerable industry, originated in England not later than the reign of Henry VIII, whose agents sought out and imported stallions and mares from the stud farms of the N. of Italy and of Spain. The studs were to a great extent dispersed during the Commonwealth. By then, however, there was no lack in the country either of thoroughbred mares or of Arabian or Barb stallions, and from the time of the Restoration there was a steady increase of thoroughbred stock, records of individual stallions and mares being kept.

The General Stud Book, first issued by James Weatherby in

William Stubbs,
British historian

1781 and published continuously since, contained the names of 387 brood mares. Subsequent research traced these and others to 49 authenticated foundation or tap-root mares, from the surviving families of which are traced all contemporary thoroughbreds.

In tail-male, all thoroughbreds descend from three imported stallions: the Byerly Turk (imported c. 1688), the Darley Arabian (imported 1704), and the Godolphin Arabian (imported 1729). From these descend respectively the Herod line, the great line of Eclipse, and the Matchem line. The origins of these male lines are undisputed, whereas the maternal lines, being of an earlier date, do not all hold the same clear titles.

The 387 brood mares recorded in the first vol. of the General Stud Book had increased to 7,904 in 1940 accounted for in Great Britain and Ireland. During the Second Great War a considerable number of mares was weeded out; as a result the annual intake of foals was reduced from a pre-war average of about 4,000 living foals to about 3,000 in 1942.

Accepted Pedigrees

The General Stud Book is not open to either a horse or mare "unless it can be traced without flaw on both sire's and dam's side of its pedigree to horses and mares themselves already accepted in earlier volumes (*i.e.* before Vol. XXII, 1913) of the book."

Stud farms, totalling perhaps 500 in all, are either privately owned establishments, whose owners breed racehorses for their own pleasure; or (a larger number) owned by public or private companies which sell the produce for profit; or (a still larger number) small studs run in conjunction with general farming.

Mares are usually retired to the stud from the age of 3, being mated for the first time at 4 years. After the foals have been born in the spring, the mares are mated again; normal procedure is that the mare, in foal, visits the stallion with whom she is to be mated; her foal is thus born away from her home paddocks, the mating taking place a few days after the foaling. Returning with her foal at foot, she proceeds to wean it until it is taken away from her in the autumn, leaving her free to nourish the new, embryo foal; the gestation period is approximately eleven months.

The stallion, usually standing at a specially equipped stud which he

alone inhabits, or shares with another stallion, holds his court from Feb. to June, when the mating season ends. He normally serves 25-30 mares in his first season at stud—usually at the age of 5 years—and 40 mares thereafter. His stud life may last for 15 years or longer. The produce, born in the following year, are foals; in the next year these become yearlings, then two-year-olds, etc.

The number of stallions at stud in 1945, including those standing at Irish studs, was slightly in excess of 600. Owners of stallions receive fees varying from a few guineas to 400 and even 500 guineas for service per mare served.

Famous studs breeding for public sales of yearlings include the National Stud, situated at Giltown in Dorset. The stud is under the direction of the ministry of Agriculture.

The foals which are bred for public sale are normally kept on the stud farms until their yearling days, having meanwhile been handled or become accustomed to environment outside their paddocks and boxes. The principal sale rings are at Newmarket (July) and Doncaster (Sept.).

The bloodstock industry fund of the animal health trust, formed 1943-44, provides facilities in research, notably into the causes and treatment of infertility and of red worm infestation in the thoroughbred. There is a scientific advisory committee, and research fellowships and scholarships. A Thoroughbred Breeders' association was formed in 1914-15. See Horse Racing.

V. E. Orchard

Studio. Workroom of a painter or sculptor. It is usually a large, lofty room, well lighted from the top and one side, preferably the N. The name is also applied to other workrooms, e.g. a photographic studio. An English monthly art magazine entitled *The Studio* was founded in 1893. It has published noteworthy supplements from time to time. See Art; Sculpture.

Studley Royal. Formerly the seat of the marquess of Ripon. It is 3 m. from Ripon. The house, which was damaged by fire in 1946, is not very notable, but the park, through which the Skell flows, is interesting, while the Dutch and Italian gardens are noteworthy. In the park are the ruins of Fountains Abbey (*q.v.*). The grounds were laid out in the 18th century by John Aislabie.

Stuka. Former German military aircraft. A twin-seater mono-

plane with a fixed undercarriage, the Stuka or Ju 87 was designed and built by Junkers. It was specially designed for dive-bombing and carried either one 1,100 lb. bomb, or one 550 lb. bomb under the fuselage and four 110 lb. bombs under the wings. The fuselage bombs carried swing links to clear the airscrew when released during a dive. The Stuka had a wing span of 45 ft. 4 ins. and a cruising speed of 199 m.p.h. Wing brakes were fitted so that it could dive with precision on special targets, such as aerodrome installations or armoured vehicles. Squadrons of Stukas worked in close cooperation with tank divs. to break up pockets of resistance. See Dive Bomber.

Stukeley, WILLIAM (1687-1765).

An English antiquary. Born at Holbeach, Lincs, Nov. 7, 1687, he studied medicine at Cambridge and S. Thomas's Hospital, London. He helped to found the Society of Antiquaries, 1718, and took holy orders, 1729, becoming rector of S. George the Martyr, Bloomsbury, 1747. Beginning with *Itinerarium Curiosum*, 1724, descriptive of antiquities observed in travel through Great Britain, he wrote many books on his subject. He died March 3, 1765.

William Stukeley.
English antiquary

Stülpnagel, Otto von (1880-1948). German soldier. He held important military appointments under Hitler, and during the Second Great War was military commander of German-occupied France, 1940-42, when he was responsible for ordering the shooting of hostages as reprisals for the killing of German soldiers and officers. During the German campaign in Russia, 1941, he shared with von Reichenau a command on the southern front, and, with the support of von Kleist's panzer divisions he advanced to Kiev, thus enabling the German forces to sweep forward over a wide front beyond the Dnieper. He was arrested by British forces in Germany, 1946, and while awaiting trial as a war criminal in Paris, he committed suicide, Feb. 6, 1948. His cousin, Karl Heinrich von Stülpnagel, who succeeded him as military commander in France, 1942, was implicated in the July plot, 1944, against Hitler and was shot by the Gestapo.

Stump-work. In art, a method of drawing formerly in frequent use with crayon or charcoal. The stump was a short, thick roll of paper, cut to a point, and with it the powdered colour was rubbed to solid tints on the paper. It was also used for softening the hard lines of a pencil or crayon drawing, or for shading.

Stupa. Dome-shaped structure erected over relics of Buddha or his sainted followers, or commemorating Jain or Buddhist events. The name is derived from a Sanskrit word meaning mound. The Hindustani variant, *tope*, is in European use. Developed from the sepulchral tumulus, its domical form was perhaps influenced by the primitive bamboo hut. Superimposed upon a drum, and crowned with a T-shaped finial, it had a processional path enclosed by a rail, with gateways, or torans, at the cardinal points.

Stupor. Partial loss of consciousness. It differs from complete unconsciousness or coma in that the person can still be roused by shouting at him, or by other strong stimuli. The condition is seen in some forms of insanity, poisoning by alcohol, opium, and other drugs, certain constitutional diseases, e.g. diabetes, and certain injuries or diseases of the brain.

Sturdee, SIR FREDERICK CHARLES DOVETON (1859-1925).

British sailor. Born June 9, 1859, he entered the navy 1871, and served in the Egyptian War, 1882, being present at the bombardment of Alexandria as a lieutenant. He was assistant-

British sailor. He was assistant to the director of naval ordnance, 1893-97, and assistant-director of naval intelligence, 1900-02. Chief of staff of the Mediterranean fleet, 1905-07, he commanded the second cruiser squadron, 1912-13.

Sturdee was chief of the war staff, 1914-15, and it was while thus employed that he inflicted defeat on the German squadron of von Spee off the Falkland Islands (*q.v.*), Dec. 8, 1914. In the battle of Jutland (*q.v.*) he commanded the fourth battle squadron. He was commander-in-chief at the Nore, 1918-21, promoted rear-admiral, 1910, admiral, 1917, and admiral of the fleet, 1921. Knighted in 1913, he was created a baronet, Jan. 1, 1916. He died May 7, 1925.

Sturdy (Old Fr. *estourdie*, giddiness). Disease of sheep. It is caused by the presence of a cyst within the brain—a stage in the development of the tape-worm of the dog, the eggs of which are expelled on grass and swallowed by sheep, passing by the circulation to the brain, and there forming the cyst. See Sheep.

Sturgeon (*Acipenser sturio*). Large ganoid fish of the family Acipenseridae. A native of both

Sturgeon. Large fish, known as a "royal fish." All caught in British rivers belong to the sovereign

sides of the N. Atlantic and the principal rivers that open thereon, in the U.K. it is an irregular visitor to the estuaries and sometimes ascends the rivers. It varies usually from 8 ft. to 9 ft. in length.

The skeleton is gristly, not bony, which is partly compensated by the head being encased in hard, bony plates, and these shields are continued in five longitudinal rows along the body. The tail is heterocercal, the upper lobe being of much greater length than the lower. The snout projects far in advance of the small, toothless mouth, and between the two hang four barbules or feelers. The single dorsal fin is placed far back, only a little in advance of the tail. It is a bottom fish, and obtains its food by grubbing with its snout in the sand and mud, obtaining worms and other invertebrates. It ascends the rivers for the purpose of spawning. An Act of parliament of Edward II constituted the sturgeon a "royal fish" belonging to the sovereign; but the lord mayor of London claimed such as were taken above London Bridge.

About twenty species of sturgeon are known, and half the number occur in Europe. The largest (*A. huso*) occurs in the Caspian, the Sea of Azov, the Black Sea, the Danube, etc. Vast numbers are taken to be eaten fresh, smoked, or salted. The roe salted, pressed, and dried forms caviare, and the air-bladder is made into isinglass.

Sturlason OR STURLUSON, SNORRI (1178–1241). Icelandic scholar. Born at Hyamm, Iceland, he was educated at Oddi, where he first became acquainted with the poetry and traditions of the skalds. Having held the supreme magistracy in Iceland, he visited Haakon IV of Norway in 1218, but failed to

execute his promise to conquer Iceland for him. After a stormy career, he was murdered at Reykholt, Sept. 23, 1241, by Haakon's orders.

His literary fame rests chiefly on his masterly prose, especially the *Heimskringla*, a history of the Norwegian kings to 1177; and his collection of the Icelandic sagas known as the Younger Edda. See Edda; Iceland.

Stuttgart. City of Germany, formerly capital of the state of Württemberg. It lies on the Neckar, 125 m. N.N.W. of Munich, in the centre of a flourishing agricultural area. Both its older streets and its modern avenues

and squares had a beauty which was much admired. The town was, however, very heavily damaged by bombing during the Second Great War, and almost all its most famous historic buildings were destroyed. Among its best-known buildings were the Stift church (12th–13th century), S. Leonard's church (15th century), the academy (1746), and the old and new palaces.

Many famous industrial plants were located there, including the Daimler-Benz motor works, the Bosch magneto factory, and various large chemical, optical, leather, paper, and food factories. It has a university, and art and other schools. Known from the 12th century, with urban rights since 1250, it became a residence of the rulers of Württemberg in the 14th century. Many famous Germans of all spheres of activity, e.g. Schiller, Schwab, and Zeppelin, were associated with Stuttgart, by either birth or residence. It was captured by the French 1st army and the U.S. 10th armoured div.,

April 22, 1945. After Germany's surrender it lay in the U.S. zone of occupation and was made capital of the *Land* of Württemberg-Baden Pop. 414,072.

Stuyvesant, PETER (1592–1672). Last governor of New Amsterdam. He was born in the Netherlands, and after serving in the West Indies he became governor of Curaçao, 1635, and in 1646 director-general of New Netherland. During his term he established better relations with the Indians, and seized the Swedish colony of New Sweden in Delaware. After the surrender of New Amsterdam (New York) to the English in 1664, he was for a short time in his native land, but returned and lived until his death on his farm called the Bouwerij (farm), which gave its name to the thoroughfare called the Bowery.

Style. In literature, mode of writing, or manner of expressing thought in language. It is generally applied to the distinctive manner peculiar to an author, or group of authors, or to a particular period or country. The French naturalist Buffon summed it up in the phrase, "the style is the man." Modern English writers regarded as stylists include Ruskin, Arnold, Pater, Stevenson, Alice Meynell, Hilaire Belloc, C. E. Montague, E. M. Forster, Charles Morgan. *Consult* Lectures on Rhetoric and Belles Lettres, H. Blair, 1783; *Miscellanies* (Lecture on Style), S. T. Coleridge, 1818; *Style*, T. De Quincey, 1859; *Style*, Sir W. Raleigh, 1897; *Appreciations*, W. Pater, 1910; *English Prose* Style, H. Read, 1928.

Style (Lat. *stylos*, a column). Botanical term for the tip of a carpel, ending in the sticky or hairy stigma which receives the pollen-grains. In some plants it is absent. See Flower; Pistil; Stigma.

Stuttgart, Germany. Air view of the city, 1945, showing devastation wrought by Allied bombing in the Second Great War

Style (from Gr. *stylos*) is also a name for the gnomon of a sundial. Style (Lat. *stilus*) is the ancient writing instrument for writing on wax-covered tablets: it was of iron or other hard material, sharp at one end for making marks, blunt at the other for obliterating them.

Styptics (Gr. *styphein*, to draw together). Drugs used to stop external bleeding. The more important are adrenalin, ergot, tannic acid, and the per-salts of iron. Local bleeding can also be arrested by applying Russell viper venom.

Styr. River of E. Europe. It rises near Brody, in Ukraine S.S.R. and takes a generally N. course of about 250 m. to join the Pripiet S.E. of Pinsk, in White Russia S.S.R. From 1921 until the Second Great War its course was in Polish territory. When the battles of the Styr in the First Great War were fought, part of its upper course divided Austrian Galicia from Russian Poland. The battles were fought between the Russians and Austro-Germans first in Oct., 1915, when, following the Russians' withdrawal from Lutsk they crossed the river near Polonne and drove the Austro-Germans westward; and again in June, 1916, when a salient of the Austro-German front on the Styr, the apex of which was at Chartorysk, was pinched out and abandoned.

Styrene. Name of an aromatic hydrocarbon, known to chemists from the first half of the 19th cent. In its simplest or monomeric form it is a colourless, lipid liquid, possessing the odour characteristic of the common hydrocarbons benzene, toluene, and xylene, to which it is closely allied. It is in fact vinyl benzene and can be represented as $C_6H_5-CH=CH_2$; it is thus a member of the vinyl family in which one of the hydrogen atoms is replaced by a phenyl group. Monomeric styrene, which boils at $145^\circ C.$, is obtained, though not commercially, in the distillation of coal tar, and as a product in the cracking of oil; and is produced synthetically by the catalytic interaction of ethylene and benzene, via ethyl benzene.

Since styrene possesses the $CH_2=CH-$ or vinyl grouping, it is capable of linking with itself to yield a polymer $(C_6H_5-CH=CH_2)_n$, where n denotes the number of monomeric units which are joined together according to the conditions of the reaction, and may vary between 100 and 200. The polystyrene thus produced is a thermoplastic, i.e. can be softened by the repeated application of heat, and

is much used in the injection moulding process (see Plastics) to make e.g. cups and saucers. Its water whiteness makes it possible to colour the material any desired shade, and transparent or opaque mouldings of great beauty are thus obtained. It is an excellent electrical insulator, and is also used in the production of laminated materials (*q.v.*).

Copolymerised with other vinyl esters, and in particular with methyl methacrylate, styrene gives a thermoplastic of excellent injection properties for dentures and dentines. Copolymerised with drying oils it gives surface coatings far superior in many ways to paint. Together with other readily polymerisable materials such as butadiene, styrene forms the basis of a series of rubber-like plastics (see Rubber: Synthetic Rubber). As a result of the demand for such substances during the Second Great War, the production of styrene in the U.S.A. increased enormously.

dead, round which it was supposed to flow seven (or nine) times. Its waters were poisonous. Styx gives the adj. Stygian. See Charon.

Suakin or SUAKIM. Seaport of the Anglo-Egyptian Sudan. It is situated partly on a coral islet in the Red Sea and partly on the mainland, and is connected by rail with Atbara Junction (308 m. S.W.) and with Port Sudan (47 m. N.N.W.). Before the construction of Port Sudan, Suakin was a commercial centre of some importance, especially for the transport of Mahomedan pilgrims for Mecca, but owing to the natural advantages of the newer port its value has declined. Suakin was occupied by the Egyptians when their power was extended over the Sudan. In the neighbourhood several battles were fought against the forces of the Mahdi. Suakin gives its name to a prov., formerly called Red Sea.

Suarez, FRANCISCO (1548-1617). Spanish theologian and philosopher. Born at Granada, Jan. 5,

Suakin or Suakim, Sudan. General view of the town, formerly an important commercial centre and Red Sea port

Styria. Former duchy and crownland of the Austrian Empire, later a division of the republic of Austria. Extensions of the E. Alps penetrate the country with decreasing elevation. The valleys of the Enns and Mur are fruitful. About half the area is forest and a fifth arable, chiefly devoted to wheat, rye, oats, and barley. Iron ore, lignite, and graphite are important mineral products and give rise to a manufacturing industry in rails, sheet iron, and wire. Graz is the capital, and Leoben, Leibnitz, and Bruck are other towns. In the N.E. the Semmering Pass (*q.v.*) carries the rly. from Vienna. Area, 6,148 sq. m. Pop. 1,085,244. See Austria.

Styrian Alps. Section of the E. Alps in Austria. The range stretches to the N.E. between the valleys of the Mur and the Enns. The Schneeberg at the E. end rises to 6,810 ft.

Styx. In Greek mythology, river of Hades, the abode of the

1548, he entered the Society of Jesus when a student at Salamanca. He became professor of theology at Segovia, Rome, Alcalá, and Coimbra. In 1613 he wrote a Defence of the Catholic Faith, which so infuriated James I of England that he had it publicly burnt. In his treatise *De Legibus ac Deo Legislatore*, Suarez touched upon international law. He died at Lisbon, Sept. 25, 1617.

Subaltern (Lat. *sub*, under; *alter*, other). Word used in the U.K. for a commissioned officer of the army who has not reached the rank of captain. Such are lieuts. and second-lieuts. See Army, British; Commission; Lieutenant.

Sub-Carpathian Russia. Name sometimes given to Ruthenia (*q.v.*) when it was an autonomous unit of the Czechoslovak republic during 1919-38. See Carpatho-Ukraine; Ukraine.

Subconsciousness. Psychological term. It is used by the more academic psychologists to

mean all mental entities below the threshold of consciousness, including that differentiated by Freud as the unconscious (*q.v.*).

Subiaco (anc. *Sublaqueum*). City of Italy, in the prov. of Rome. It is situated on the Teverone, the ancient Anio, 47 m. by rly. E. of Rome. Walls and terraces of one of the villas of Nero are still to be seen on the opposite side of the valley from the three monasteries, the first of which, Santa Scolastica, was founded by S. Benedict in 530. Here in 1465 was printed the first book published in Italy. During the Second Great War one wing, a modern addition, of the Santa Scolastica was destroyed by bombs. The town was shattered during the German retreat of 1944, when a mass of vehicles was trapped in the main street and wiped out by bombing from the air. The 8th army entered Subiaco June 8. Pop. est. 8,000. See Benedict, S.

Subject (Lat. *subjectus*, put under). Philosophical term used in three different senses, as opposed to attribute (predicate), quality, and object. As opposed to attribute, it stands for that of which the attribute is affirmed. The subject is the more important of the two ideas which every judgement necessarily contains. In metaphysics, as opposed to quality, subject is often used as a synonym for substance. In this sense, it is a being regarded as integral and permanent, representing the union in space and time of its manifold and shifting phenomena.

Since the time of Kant, however, subject is more commonly opposed to object. In this sense it is used for the Ego, the thinking subject, the soul which thinks. The subject is the mind that thinks; the object is that about which it thinks. A subjective impression has its origin in the mind itself; an objective impression is due to the observation of external things. Subjective refers to the immediate appearance or impression, objective to that which we recognize from that appearance as appearing in it. In other words, subjective refers to the appearance as such, or to the appearance in its immediate relation to the Ego or thinking subject to which it appears; objective to the knowledge of the appearance or object.

It should be noted that the schoolmen used the terms subjective and objective in an exactly opposite sense. To them subjective meant that which was real, that which belonged to things as

they were in themselves; objective that which was ideal, that which belonged to things according to the manner of their presentation to consciousness.

Subject. In music, a theme or sentence upon which a composition is founded. A fugue subject is generally concise. The subjects in a sonata (*q.v.*) are of greater length, and may comprise more than one sentence, and include several distinct ideas. The earliest form of subject was the Cantus Firmus which, put into long notes, formed the thread on which the composer wove various devices of imitation.

Subjunctive (Lat. *subjunctivus*, joining on at the end). In grammar, the mood of contingency or uncertainty, preceded by a conjunction expressed or understood: were he alive; if it be. In most languages it plays an important part; in English almost the only survivals are *be* and *were*, and it seems likely that even these will eventually disappear.

Sublimation (Lat. *sublimare*, to raise). The passing of a solid substance into vapour without melting. The vapour is similarly condensed by cold direct to the solid state. Sublimation is carried out in vessels made of iron, glass, or earthenware, and the process is employed for purifying various materials, such as iodine, sulphur, naphthalene, ammonium chloride (sal ammoniac), and camphor. Flowers of sulphur is a sublimation product.

In psychology, the term is used to indicate the diversion of mental energies, which might lead to

harmful or anti-social results, into useful channels.

Sublime Porte. This term, formerly used for the govt. of Turkey, is described under *Porte*.

Subliminal Self (Lat. *sub.*, below; *limen*, threshold). In psychology, a term for the subconscious mind, used especially by those who regard it as the fundamental self, of much wider scope than the empirical self of normal waking consciousness. This school, following F. W. H. Myers and W. James, holds that in the evolutionary process only so much has emerged as the practical ends of physical life require, the rest of the personality, unknown to the empirical self, remaining in contact with other minds, drawing energy from a spiritual reservoir transcending individuality, and in certain exceptional persons overflowing and manifesting itself in the hypnotic trance, telepathy, clairvoyance, inspiration, and the intuitions of genius. See Hypnotism: Psychical Research.

Sublingual Gland. Smallest of the salivary glands, lying beneath the tongue on each side. See *Saliva*.

Sub-Machine-Gun. Type of machine gun that can be carried and fired by hand like a rifle or revolver. It may be fed by box or drum magazine and generally fires ammunition of .45 calibre or lower. The first was the Thompson ("tommy") gun introduced in the U.S.A. and used by gangsters and police. In the Second Great War sub-machine guns were adopted by all belligerent armies as weapons for close fighting.

SUBMARINE AND SUBMARINE WARFARE

Francis McMurtrie, Editor, *Jane's Fighting Ships*

The history of the undersea warship called a submarine is here followed by an account of the German U-boat war in the First and Second Great Wars. See Atlantic, Battle of the

Up to 1945 the submarine could have been defined as a vessel which normally cruised on the surface, but was designed to dive and operate under water when required. This definition is no longer exact. In fact, trials have proved that a submarine can operate submerged for weeks if necessary without ill effects upon her crew.

Streamlining has become an outstanding characteristic of a submarine's hull, which is normally of circular section. To take a submarine beneath the surface, water is admitted into the ballast and trimming tanks until buoyancy becomes negligible, the actual operation of diving being effected

by the use of hydroplanes, or horizontal rudders. When it is desired to return to the surface, water is expelled from the tanks by the use of compressed air, of which a large supply is carried in air bottles made to withstand high pressure.

Diesel engines are the normal method of propulsion on the surface and electric motors below, though experiments with other agents have made progress. Surface speeds have seldom exceeded 20 knots in service, and have often been below that figure. Submerged speeds, which used to be below 10 knots, may well increase until they equal those on the surface.

Auxiliary machinery, such as pumps, air compressors, tele-motor

Submarine. Longitudinal section of a U.S. submarine of the Second Great War showing the interior arrangements for accommodation, navigating, and fighting

gear, etc., take up an appreciable amount of the severely limited space in a submarine. Still more is occupied by the torpedoes and the tubes from which they are discharged; these vary in number according to the size of the submarine. The torpedo is the prime weapon of the submarine, such light guns as may be mounted on the superstructure being merely secondary armament. In the U.S. navy much interest has been aroused by the experiment of launching a guided missile, or rocket, from a submarine.

For some three centuries submarines were the subject of more or less disappointing experiments by inventors. Bourne, in 1578, was probably the earliest of these, though the Dutchman, Cornelis Drebbel, in the reign of James I has often been given the credit of being the pioneer. The first submarine to go into action was devised by David Bushnell, a Yale graduate who in 1776 attempted unsuccessfully to destroy ships of the British fleet off the New England coast by this means. A quarter of a century later another American, Robert Fulton, produced a submarine which failed to win approval from either the British or French government, to both of whom he had submitted it.

During the American Civil War the Confederate navy built a number of semi-submarines called "Davids," which gained minor successes against the blockading Federal fleet. The next notable development was the construction during 1885-91 by the Swedish inventor, T. Nordensfeldt, of six submarines, in designing which he had the collaboration of the Rev. G. W. Garrett, of Liverpool. The first of these was sold to the Royal Hellenic navy, the second to Turkey, the third to Russia. The remaining three were built at Kiel and Danzig to the order of the German navy.

In the decade that followed, substantial progress was made in submarine design, more especially by A. M. Laubeuf in France and by J. P. Holland in the U.S.A. Not until 1902 were the first British submarines placed in com-

mission; these were of American design, built at Barrow-in-Furness. Under the direction of Captain (afterwards Admiral Sir Reginald) Bacon, exhaustive trials were made with these experimental craft, and a much improved design prepared for the "A" type, the first entirely British submarine. One of the important new devices in these submarines was the periscope, for the idea of which Bacon himself was responsible.

In the intervening years before the outbreak of war in 1914, this type was steadily developed and improved until a design that would stand the test of action was evolved. Between 1914 and 1918 submarines of the Royal Navy were successful in destroying 30 enemy warships.

In that war the Germans devoted much energy to the construction of submarines, with which they attacked Allied and neutral shipping. Ignoring all the accepted rules of naval warfare, they torpedoed merchant vessels without warning and left them to founder. The revival of the convoy system, coupled with the provision of larger numbers of escort vessels armed with depth charges and equipped with anti-submarine devices, in the end overcame the menace of the German U-boat.

Experiments with Large Vessels

Immediately after the First Great War there was a short-lived demand for large submarines, the outstanding examples being the British X 1, of 2,425 tons surface displacement; the U.S. Nautilus design of 2,730 tons; and the French Surcouf of 2,880 tons. None of these experimental vessels gave satisfaction in service, and vessels of moderate dimensions continued to be preferred.

Between the wars British submarines developed from the "L" class of 845 tons, armed with six torpedo tubes, to the "T" class of 1,090 tons, with either nine or eleven tubes. Similarly, the U.S. navy progressed from the 850-ton "S" type, with four tubes, to the Gato type of 1,525 tons with ten tubes.

During the same period the Germans were precluded by treaty from building submarines. They contrived, however, to maintain close touch with submarine design, their experts being responsible for various building projects in other countries.

In the Second Great War the German submarine onslaught was even more formidable than it had been 20 years earlier. Starting with the sinking of the liner

Athenia on the first day of hostilities, the conflict with the U-boats raged for 68 months, during which 2,775 British, Allied, and neutral merchantmen, aggregating 14,500,000 tons gross, were destroyed. Lives lost in these vessels numbered about 35,000.

Both sides began the war better prepared than in 1914. The Germans had 57 submarines of up-to-date design, with more nearing completion; but the British asdic detection device had been considerably improved since 1918 and was installed in most destroyers and escort vessels. No time was lost in instituting a system of convoy; but there were never enough escorts to meet all the demands, in spite of the extensive building programmes that were put in hand, putting under the control of the Admiralty by 1944 as many as 880 asdic-fitted vessels engaged on ocean convoy work.

Effect of French Capitulation

Up to June, 1940, the submarine attack was held in check, but with the capitulation of France the western European coastline from Tromsø to Bordeaux came under German control, providing numerous bases on the flanks of the British Isles and the Atlantic convoy routes. At the same time that the attackers were reinforced by about 100 Italian submarines, the defence was weakened by the French navy's withdrawal and Great Britain's severe losses in destroyers at Dunkirk. Thus for the ensuing 18 months the Royal Navy had to contend single-handed with the U-boats, which soon adopted novel tactics to baffle the asdic device. Shadowing a convoy at extreme range during the day, they would close in on the surface at night, fire their torpedoes, and escape at full speed, only diving in emergency. This technique was developed into the so-called "wolf pack" system, by which a whole flotilla of U-boats would be concentrated on a convoy after dark. As a countermeasure, escort vessels were fitted with radar for the detection of surfaced U-boats. Later, as an additional defence measure, some merchant vessels were equipped with a catapult and a single-seater fighter for use in emergency. Once flown off, however, the aircraft could not return to the ship. In due course a number of tankers were fitted with flight decks so that they could carry aircraft which could be flown off and back again. Both measures were temporary expedients, pending completion of an adequate number of escort carriers.

The main Axis concentration was observed to move farther west across the Atlantic; this made interception by escort carriers more difficult, few having the necessary fuel endurance. A number of escort carrier groups and Coastal Command squadrons were based in Iceland; but there was still left in mid-Atlantic a gap which could not be covered by long-range aircraft from the British Isles or Canada.

With the entry of the U.S.A. into the war in Dec., 1941, the U-boats were presented with a fresh field of operation off the American E. seaboard: Jan. to July, 1942, casualties in this area amounted to 495 ships of over 2,500,000 tons gross, including 142 tankers of more than 1,000,000 tons. In the same period 42 German and Italian submarines were lost.

New devices introduced about this time included the hedgehog, a spigot mortar firing ahead of a ship a salvo of 24 depth charges, each containing 32 lb. of explosive; and the Leigh light, by the use of which, in conjunction with radar, aircraft could sight and attack U-boats on the surface at night.

The ten months from Aug., 1942, to May, 1943, saw the peak of the enemy effort and foreshadowed its final defeat. German submarines were built faster than they could be destroyed, and there were usually from 80 to 100 at sea at one time. Very long-range aircraft were now able to carry out attacks on U-boats 600 m. from their bases. This helped materially to break up the "wolf packs," though merchant losses continued heavy.

The destructive effect of depth charges was increased by the introduction of a new explosive, minol, which could crack the pressure hull of a U-boat at 25 ft.

Attempt to Nullify Radar

In an effort to nullify Allied radar, the Germans had equipped their submarines with a device known as a search receiver; but British scientists very soon effected a modification in the radar equipment of escort vessels and aircraft which successfully overcame this obstacle.

Early in June, 1943, the U-boats, dismayed by heavy losses, had virtually been withdrawn from the N. Atlantic convoy routes, though some 80 were still at sea. U.S. escort carriers, whose aircraft delivered a number of successful attacks, helped to fill the mid-Atlantic gap. Though the A.A. armament of the U-boats had been materially augmented, little was gained by this. Close cooperation

between surface escorts and aircraft had yielded such excellent results that these tactics were now extended to deal with U-boats on passage to and from Biscay ports.

In Sept., 1943, the Germans resumed attacks on Atlantic convoys with the aid of a new weapon. This was the acoustic torpedo, which "homed" on to its target by the noise of propellers. All German submarines were provided with three or four of these weapons, the idea being to use them to destroy the escort vessels and then use ordinary torpedoes against the merchant ships. With British acquisition of bases in the Azores in Oct. the gap in mid-Atlantic was really closed, and the strength of anti-submarine sea and air defence became so great that Oct. saw the last large scale "pack" attack. So difficult had it become for U-boats to avoid detection by radar when they came to the surface at night to recharge their batteries that the Germans adopted a breathing device called the schnorkel (*q.v.*), eventually fitted to all U-boats, which made their detection from the air almost impossible.

Heavy U-Boat Losses

In the first six months of 1944 the enemy lost 122 submarines. No effective interference from U-boats was experienced during the Normandy campaign. Later in the year another new anti-submarine weapon was brought into service: the squid, a three-barrelled mortar firing with great accuracy a pattern of large charges ahead of a ship.

The bulk of the German submarine effort was maintained by vessels of two types, the smaller displacing from 626 to 753 tons on the surface and the larger more than 1,000 tons. Maximum surface speed of the former was 16-17 knots, with an extreme range at low speed of 11,000 m. Corresponding figures for the larger type were 18 knots and 15,000 m. These ranges could be and were extended indefinitely by the use of supply submarines of larger size.

Towards the close of the war the Germans produced a 1,600-ton submarine with a streamlined hull designed to operate almost continuously submerged, in which condition the maximum speed was about 15 knots. Though 120 of these were built before the war ended, very few of them had gone into operation at the time of the German surrender.

In the closing months the number of merchant vessels lost each month was frequently exceeded by the total of U-boats destroyed. In

Feb., 1945, there were still 60 German submarines operating, mostly based on Norwegian ports. In May, the month of surrender, three ships were sunk by U-boats, but 25 of the latter were lost, mostly through Coastal Command attacks.

From first to last 778 German submarines were destroyed out of a total of 1,155 completed. The Italians lost about 100, several of which had previously fallen into German hands. Japanese submarine losses totalled 131. These figures exclude submarines of the midget category, which in enemy hands had little success.

During the war the Japanese built three submarines of about 5,000 tons, with a speed of 21 knots. No useful purpose was served by these huge vessels, which fell into American hands at the surrender. In general, Japanese submarines failed to accomplish much, whereas those of the U.S. navy scored many successes, ultimately wiping out the greater part of the Japanese mercantile fleet.

Typical post-war submarine types included the British "A" class, of 1,120 tons displacement, armed with 10 torpedo tubes. Surface speed was 18 knots, and the "snort," a British adaptation and improvement of the German schnorkel device, was included in the equipment. Construction was all-welded. Later came the U.S. Tang type, reported to displace 2,000 tons and to embody various improvements due to war experience, including a type of propulsion expected to give higher underwater speed. Another novel American type was specially designed and equipped for hunting enemy submarines.

Submarine Canyons. In geology, deep valleys entrenched in the slope connecting the continental shelves with the ocean depths. Such canyons are comparable in size with the biggest land valleys, having depths up to 4,000 ft.; some have been traced to 10,000 ft. below sea level. They are known to be of fairly recent formation, because Pliocene rocks have been dredged from their slopes. Their origin is still debated.

Submaxillary Gland. Salivary gland situated on the inner side of the angle of the lower jaw on each side. *See* Saliva.

Submerged Forests. Remnants, usually roots and stumps, of old wooded areas covered by the sea. They are visible only at low tide, and afford evidence of recent movements of land rela-

tive to the sea, or vice versa. Examples can be observed in several localities around the British coast, e.g. Cheshire and Lincs.

Submerged Tenth. Term used by William Booth (*q.v.*) in his book *In Darkest England*, 1890, to describe the hopelessly destitute class of society whose number Booth estimated at one-tenth of the population of Great Britain. Primarily to assist them through spiritual and practical guidance, he founded the Salvation Army (*q.v.*).

Sub-ordinaries. In heraldry, conventional symbols, simple in form like the ordinaries (*q.v.*) but of secondary importance. Seven of these are generally recognized: (1) the gyron (*q.v.*); (2) the fret (*q.v.*); (3) the inescutcheon; (4) the border, a broad band round the shield; this has two diminutives, the orle (*q.v.*) and the tressure, a smaller orle and generally borne in couples, one within the other; (5) the pall (*q.v.*) or pallium; (6) the flanche (*q.v.*), with its diminutives the flasque and the voider, respectively half and a quarter the size of the flanche; (7) the lozenge. *See* Heraldry colour plate.

Subornation (Lat. *sub*, under; *ornare*, to provide). Crime of procuring another person to commit an illegal act. As a legal term it is virtually restricted to subornation of perjury—instructing or inducing another to give false evidence on oath; an offence involving the same punishment as perjury itself.

Subotica (Hung. Szabadka). Town of Yugoslavia, formerly in Hungary. It is the largest town and the chief rly. junction in the Bačka, the dist. between the Theiss and the Danube, which passed from Hungary to Yugoslavia by the treaty of Neuilly, 1919. It is the centre of the richest cereal-producing dist. in the country, and has considerable trade in horses and swine. Belgrade university has a law faculty here. Linens, leather, and boots and shoes are manufactured. Pop. 100,058. *Pron.* Soobotetsa.

Subpoena (Lat., under a penalty). Writ issued out of a court of justice, commanding the person to whom it is addressed to be present in court at such a time, under a penalty if he fails to comply. It is used now only as a means of compelling the attendance of witnesses, and such a subpoena is called *subpoena ad testificandum*. A *subpoena duces tecum* is a writ ordering a witness to bring to court documents or other things in his possession. Disobedience to

a subpoena is generally punished by a fine.

Subrogation. In law, the substitution of one person or thing for another. It is specially used in connexion with insurance contracts taken over by an underwriter. He is subrogated to the insured, i.e. is entitled to everything that would fall to the insured person under the contract. A variant of subrogate is surrogate (*q.v.*). *See* Insurance; Substitution.

Sub Rosa (Lat., under the rose). Privately, or in strict confidence. The rose was a symbol of silence, and was carved on confessional boxes, and also on the ceilings of banqueting halls, where it is said that it indicated that guests should not repeat incautious utterances made under the influence of wine.

Subsidence. Term used in geology for the sinking of portions of the earth's crust. Such movements take place from a number of causes, e.g. erosion and weathering of rock masses, which slowly bring into play, due to unequal distribution of land, forces great enough to bring about a warping of the earth's crust. Such subsidences are constantly taking place on a large or small scale. The land is slowly subsiding on the W. coast of Greenland, on the Italian coast near Naples, and on the E. coast of N. America. Smaller scale subsidences are the result of solution at depth, e.g. of limestone, causing collapse of the surface. Subsidence may also occur above coal or salt mines. The term is also used in meteorology to denote the slow downward movement of air from the upper layers of the atmosphere. *See* Erosion; Geology; Rift Valley; Rock.

Subsidy (Lat. *subsidiūm*, aid). A payment of money to support a person or a project. Originally, when the expenses of government were defrayed out of the king's income, subsidies were votes of money to the king by parliament; until the reign of Edward III the chief business of parliament was to vote such subsidies. (*See* Tonnage and Poundage.) From early times the word was also applied to aid given by one country to another. Thus Afghanistan was for many years subsidised by Great Britain to secure her neutrality. During the First Great War, Great Britain subsidised many of her allies; subsequently she subsidised the White Russians. During the Second Great War many subsidies took the form of

Lease-Lend (*g.v.*). After the war the U.S.A. continued to subsidise European recovery.

The principal use of the word subsidy in the 20th century has been to denote payments from govt. funds, *i.e.*, taxation revenues, to support economic or social policy, particularly payments to encourage the production of certain commodities or to maintain prices at a desired level. Thus in Great Britain from 1933 subsidies were paid to encourage production of milk, and of better quality milk, and the increased drinking of milk, especially by school children. Similarly the production of beet sugar, fat cattle, coal, and other commodities was subsidised before 1939. During the war the production and marketing of commodities, particularly food-stuffs, were controlled centrally; most subsidies took the form of payments to cover the difference between the prices guaranteed to producers and those charged to consumers. In this way the cost of living was subsidised in a largely successful attempt to avoid inflation. Food subsidies cost about £400,000,000 during 1948-49. Most British subsidies are paid out of taxation revenue; but some, such as those for housing, are normally met partly out of local taxation, *i.e.*, rates.

Substance (Lat. *sub*, under; *stare*, to stand). In philosophy, that which has a permanent, independent existence contrasted with its accidents (inessential qualities), which are variable, and have no independent existence. Substance, then, will mean that which supports the accidents, makes their existence possible; in reference to its permanent existence, the word is sometimes derived from *subsistere* (to subsist). The chief views of substance are: (1) Since nothing is permanent, the idea of substance is a pure fiction. (2) There is an absolute, infinite substance, of which all beings are only "modes" (Spinoza). (3) There are no sensible substances, the world is known to us only by the action of God on our mind. Substance is not a separate thing over and above phenomena, but a simple form of thought applied to the myter of knowledge, the reality of which, however, we cannot affirm, since such an affirmation would transcend the limits of experience. The category of substance expresses only the necessary connexion of phenomena in space and time; beyond the phenomena, substance is an un-

known quantity (Kant). (4) Substances are only permanent bundles of impressions (Hume, Mill).

Substantive Rank. In the British army, military rank which counts for pay and pension, as distinguished from brevet or honorary rank. *See* Officer.

Substitutions. In mathematics, the theory of the replacement of a set of algebraic variables by another set connected with the first by a system of equations equal in number to that of the variables in either set. The theory, which belongs to the domain of higher mathematics, has many important applications, especially in projective geometry and methods of analytical treatment of curves and surfaces. By means of the theory it was shown that the quintic or equation of the fifth degree could not in general be solved. *Consult* Theory of Groups of Finite Order, W. Burnside, 1911; Homogeneous Linear Substitutions, H. Hilton, 1914.

Subway. Construction underneath the main arteries of traffic in large cities for sewers, gas and water pipes, electric light, telephone and telegraph cables, etc., also for foot passengers. A subway has a cross-section of sufficient size to give plenty of room for workmen, and is provided at intervals with entrances and ventilating shafts.

Another form enables foot passengers to pass under streets at points where traffic is congested, or gives communication between rly. stations, and the platforms of a big station.

A subway for electric trams runs from Southampton Row to the Embankment, London. The New York underground rly., which is commonly called the subway, runs the whole length of Manhattan Island and passes under the East river to Brooklyn. *See* Bank; Blackwall; Greenwich; Railways; Rotherhithe; Tunnel.

Succession (Lat. *succedere*). Literally, to go up and therefore to follow. It is applied to the act of ascending a throne when in accordance with the laws governing such an event. In the United Kingdom this is regulated by the Act of Settlement (*g.v.*). Legally it means the taking of property which comes to one on the death of another. The duties levied in the United Kingdom and other countries, including the U.S.A., on such property are called legacy or succession duties. The term is also used for the assumption of a title owing to the death of

the previous holder, and in other related senses, *e.g.* the succession or rotation of crops. *See* Apostolic Succession; Death Duties; Legacy Duty; Primogeniture.

Succession Duty. Duty formerly payable in the U.K. on property which passed from one person to another upon death. It was payable whether the transfer was by gift or by inheritance, but was not payable where the estate was liable to legacy duty. The rate at which succession duty was paid depended on the relationship between the person succeeding and the predecessor. Where the successor was the husband, wife, descendant, or ancestor of the predecessor the rate was 2 p.c.; if brother, sister, or descendant of brother or sister, it was 10 p.c.; for more remote relations it was 20 p.c. Succession duty was abolished in 1949 in respect of deaths after July 29, 1949.

Succinic Acid (Lat. *succinum*, amber), (CH₂COOH)₂. Solid acid, usually prepared by the dry distillation of amber, or made by fermenting ammonium tartrate. In the former process amber is subjected to dry distillation in a retort, when it is decomposed into amber oil (spirit of amber), amber resin, and succinic acid. The last named is a yellow-coloured crystalline substance. The salts of succinic acid are known as succinates, and are used in medicine. *See* Amber.

Succoth (Hebrew, booths). Name applied to the first camping place of the Israelites when they left Rameses, and also to a resting place of Jacob near Shechem. The name is also applied to the Jewish feast of tabernacles, which is celebrated at a date falling in Sept. or early Oct.

Succulent Plants (Lat. *sucus*, juice). Plants whose leaves and shoots, sometimes the entire plant, are swollen because their tissues store up great quantities of fluid. Such a condition denotes that the natural habitat of the plant is either the desert, dry rocks, or the sea-shore. In the desert, where rain falls only at long intervals, perennial plants could not survive if they had no means of storing moisture, which they absorb in quantity during the rainy period. Their cuticles are leathery, and permit little evaporation. Examples are afforded by the Cactaceae, some of the euphorbias, agaves, and aloes. Rock-plants such as sedums and sempervivums are subject to similar conditions, because their roots have little soil, which rapidly dries up. *See* Botany; Plant

AIDE-de-CAMP'S LIBRARY
